SECTION 1 – PREFACE

This manual is intended for use as a technical reference by developers, planners, engineers, government officials and others involved in land use planning, building site development, and natural resource conservation in rural and urban communities and developing areas.

The standards and associated materials describe best management practices (BMPs) for controlling non-point source pollution impacts that affect ecosystems in existing communities and developing areas. The manual includes an array of BMPs in the following broad categories:

- soil erosion and sediment control;
- stormwater management; and
- special area protection.

Beyond conventional BMP considerations, the manual addresses fish and wildlife habitat improvement, visual and environmental quality and other relevant ecosystem enhancement applications. Where previous BMP manuals have tended to focus on limited aspects of construction site erosion or stormwater runoff control, this manual is designed for more comprehensive, multi-objective ecosystem protection and enhancement.

This manual supersedes the Illinois EPA's 1987 *"Standards and Specifications for Soil Erosion and Sediment Control"* (commonly known as the "Yellowbook") and the original "1995 Illinois Urban Manual." It also replaces Chapter 6, entitled "Procedures and Specifications", of the Association of Illinois Soil and Water Conservation District's 1988 *"Procedures and Standards for Urban Soil Erosion and Sedimentation Control in Illinois"* (commonly known as the "Greenbook").

This manual was prepared for the Illinois Environmental Protection Agency (EPA) by the United States Department of Agriculture's (USDA) - Natural Resources Conservation Service (NRCS) in Illinois. The NRCS was formerly known and recognized as the Soil Conservation Service (SCS). Initially released in 1995, the manual is being revised by a committee made up of federal and state resource agencies, regional planning commissions, local units of government, and the private sector.

Funding in part for the development and maintenance of this manual was provided by Section 319 of the Clean Water Act through Illinois EPA.

This section was revised in November 2002.

The U. S. Department of Agriculture (USDA) prohibits discrimination in all its programs and activities on the basis of race, color, national origin, sex, religion, age, disability, political beliefs, sexual orientation, or marital or family status. (Not all prohibited bases apply to all programs). Persons with disabilities who require alternative means for communication of program information (Braille, large print, audiotape, etc.) should contact the USDA's TARGET Center at (202) 720-2600 (voice and TDD). To file a complaint of discrimination, write USDA, Director, Office of Civil Rights, Room 326-W, Whitten Building, 1400 Independence Avenue, SW, Washington, D.C., 20250-9410, or call 1-202-720-5964 (voice and TDD). USDA is an equal opportunity provider and employer.

SECTION 1 - INTRODUCTION

This manual is intended to be a dynamic document. Several sections may stay static for long periods of time. Others, such as sections 4, 5, 6, and 7, will likely be expanded on a regular basis to include additional conservation practice standards, construction specifications, material specifications and standard drawings not yet developed.

This manual sets no policy, rules, regulations or restrictions. However, it is anticipated that various units of government and local, state, or federal agencies would use these technical materials to guide development of policy, ordinances, restrictions, or regulations. If adopted by reference in a regulatory program, such as in a Soil Erosion and Sediment Control Ordinance adopted by a local jurisdiction, the contents of the manual have the force of law.

No individual section of this manual will contain all the guidance or material necessary to fully assist users to develop or implement site specific plans. Other references or sections of other manuals or handbooks that supplement this publication should be utilized as appropriate. Other primary reference materials to support this manual are listed in the References section of the practice standards or in Section 9 - References. All references to IDOT in the practice standards and on the standard drawings refer to the *Illinois Department of Transportation Standard Specifications for Road and Bridge Construction*, Adopted January 1, 2002. The standard drawings use an 'RR' designation in place of a gradation number. Assume the 'RR' to be synonymous with 'Gradation'.

Users of the manual are encouraged to contact the following if you have any questions or additional information or assistance is needed:

1. NRCS/SWCD County Office (in the phone book under U.S. Government, Department of Agriculture or the Illinois NRCS website www.il.nrcs.usda.gov under "Directories"), or
2. Illinois EPA, Bureau of Water - Watershed Management Section, 1021 North Grand Avenue East, PO Box 19276, Springfield, IL 62794-9276 (phone 217-782-3362), website: www.epa.state.il.us/water/index.html, or
3. NRCS State Office at 2118 W. Park Court, Champaign, IL 61821 (phone 217-353-6600); or
4. Kent Sims, NRCS Community Assistance Specialist, at 313-J Naperville Rd., Plainfield, IL 60544 (phone 815-577-3597), Email at Kent.Sims@il.usda.gov.

Materials found in this manual can be electronically accessed and are available through the Illinois NRCS website www.il.nrcs.usda.gov under "Technical Resources" or the URL address www.il.nrcs.usda.gov/engineer/urban.

This section was revised in November 2002.

SECTION 2 - NONPOINT SOURCE POLLUTION CONTROL PROCESSES AND PLANNING PRINCIPLES

INTRODUCTION

This section is intended to provide a basic understanding of non-point source (NPS) pollution processes and the principles for minimizing or preventing their effects. These principles must be understood in order to facilitate a comprehensive management strategy, including the design and application of techniques which can effectively control undesired consequences of urban development.

Although this manual is primarily developed to address non-point source impacts, other considerations also need to be addressed. Total natural resource planning will include components that address soil, water, air, plant, and animal resources. In addition, the human aspect of cultural, social, and economic issues needs to be considered.

While this section does not provide a complete discussion of the many issues that should be considered to develop an effective NPS pollution control plan, it does provide a general description of the following key principles and processes:

- A. Overview of Non-point Sources and Impacts;
- B. Planning Principles for Selecting and Implementing Best Management Practices (BMPs);
- C. Soil Erosion and Sediment Control;
- D. Stormwater Management; and
- E. Special Area Protection.

Most NPS pollution control plans will be prepared, and BMPs designed, to meet the requirements of existing ordinances or other governmental or agency regulations or codes. These requirements must be clearly understood so that planning can proceed in a timely and cost effective manner. However, considering the limited scope of many local ordinances, it is strongly recommended that NPS pollution control plans, and site designs, go beyond the required components to address resource concerns in a holistic, multi-objective manner.

This section was revised in January 1999.

A. OVERVIEW OF NONPOINT POLLUTION SOURCES AND IMPACTS

Recent reports acknowledge that a principal water quality problem in our Nation is non-point source (NPS) pollution. The U.S. Environmental Protection Agency (USEPA) defines NPS pollution as precipitation driven stormwater runoff, generated by land-based activities, such as agriculture, construction, mining, or silviculture. These activities result in diffuse runoff, seepage or percolation of pollutants from the land surface to ground and surface waters.

The Illinois Environmental Protection Agency (EPA) has documented the nature and degree of NPS pollution impacts throughout the State. Numerous watershed assessments have further documented these impacts. To put non-point sources of pollution and the need for their control into perspective, the Illinois EPA first evaluates streams, lakes, and other aquatic ecosystems with respect to their ability to support designated uses, such as aquatic life or swimming. If a use is impaired, causes are identified. Typically, a number of sources, both point and non-point, are identified as contributors. Finally, a list of appropriate BMPs is provided to control the identified non-point sources. While this manual focuses on the selection, design, and implementation of those BMPs, it is important to understand the linkage between BMPs, non-point sources, causes, and use impairments to appreciate the importance of a multi-objective management plan.

A notable distinction between the USEPA definition of non-point source pollution, cited above, and Illinois EPA's definition is the recognition that non-point sources affect not just water quality but also the physical habitat of aquatic ecosystems. The Illinois EPA identifies eight basic categories of NPS pollution which encompass agricultural, urban, and special land development activities (e.g., mining). This manual focuses on NPS pollution in the following categories:

- erosion from construction sites;
- urban runoff; and
- hydrologic/habitat modification.

Development has both direct and indirect impacts on water bodies and other valuable natural features. These impacts occur both during construction and after the development is complete. Some impacts result from the direct modification or destruction of streams, lakes, and wetlands. Other impacts occur primarily offsite due to changes in the quality and quantity of runoff from the development. Some common NPS pollution sources from development are described below.

1. Erosion from Construction Sites

Erosion and sedimentation are natural geologic processes that human activities often accelerate. Erosion occurs through the action of water or wind. In Illinois, water is the primary cause of erosion. Wind erosion in urban areas is a minor concern, but it can be

a nuisance and even a safety hazard in areas near a site under development.

There are three major processes that must be understood to effectively control or limit soil erosion and sedimentation on construction sites. These are detachment, transport, and deposition. Four types of erosion showing detachment and transport of soil on an exposed slope are shown in Figure 2.1. The four erosion types are as follows:

Raindrop erosion is erosion resulting from the direct impact of falling drops of rain on soil particles. This impact dislodges soil particles and splashes them into the air. The dislodged soil particles can then be easily transported by the flow of surface runoff.

Sheet erosion is the removal of a layer of exposed surface soil by the action of raindrop splash and runoff. The water moves in broad sheets over the land and is not confined in small depressions.

Rill and Gully erosion occurs after runoff flows concentrate into rivulets, cutting several inches deep into the soil surface. These grooves are called rills. Gullies may develop from rills if not repaired or in other areas where a concentrated flow of water moves over the soil.

Stream and Channel erosion occurs with an increase in the volume and velocity of runoff. These larger and faster flows detach and then transport soil from the stream bottom and the stream bank toe. If not repaired, large sections of the stream bank may fail or slump into the stream.

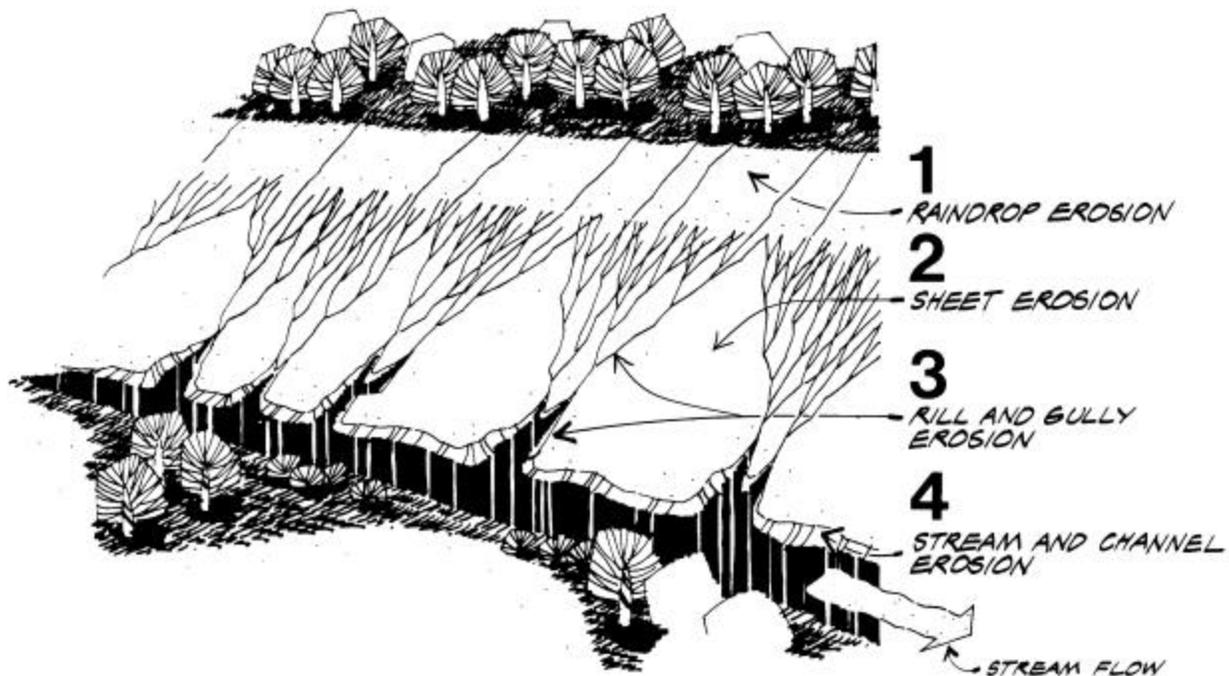

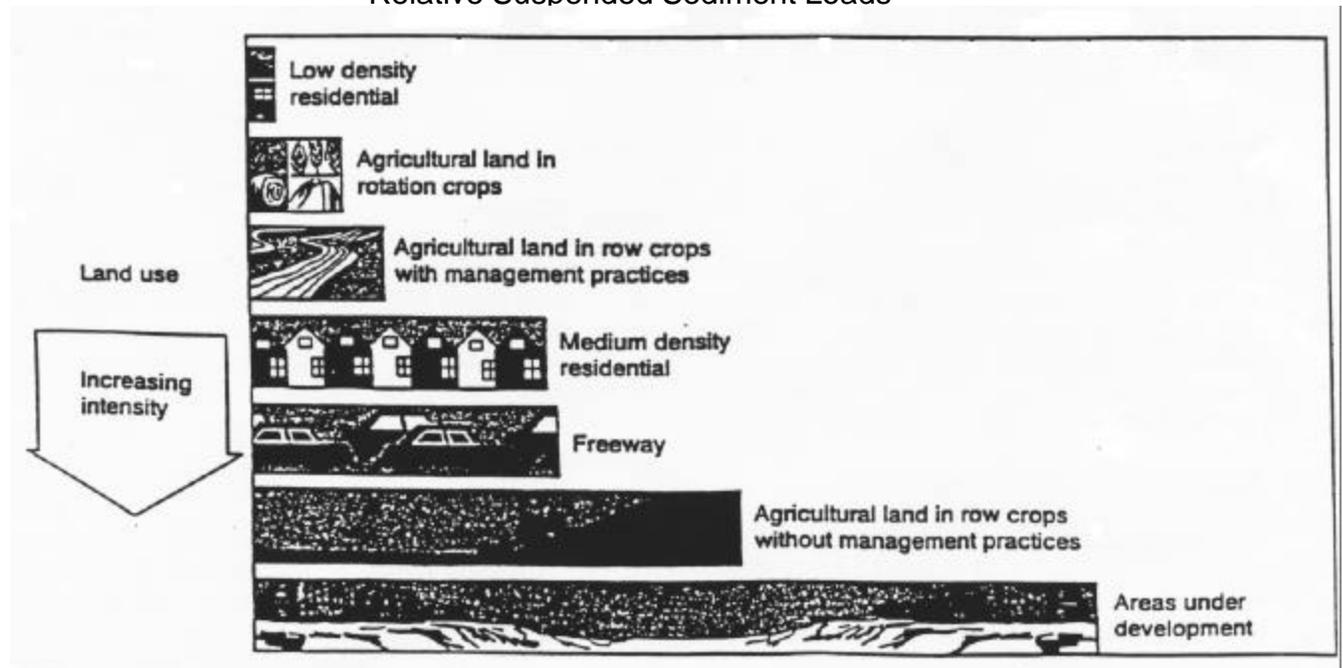

Figure 2-1 The Four Types of Soil Erosion on an Exposed Slope

Many of the BMPs included in Section 4 of this manual will individually address one or more types of erosion. Of these, most will impact the detachment or movement of sediment or provide storage methods.

National estimates indicate that uncontrolled erosion from construction activities can generate enormous quantities of sediment -- 20 to 200 tons per acre per year. In comparison, typical erosion rates from croplands range from 1 to 20 tons per acre per year. Figure 2-2 shows a relative comparison of suspended sediment loading, again indicating the relatively high contribution of sediment from construction sites.

Relative Suspended Sediment Loads

Adapted from Wisconsin Department of Natural Resources
Figure 2-2 Sediment Losses Related to Land Use Practices

Construction site erosion and the movement of sediment as it leaves the site causes several offsite problems. Also, a site that has been degraded from excessive erosion is more expensive to landscape and maintain. The resultant sediment deposits are expensive to remove from culverts, ditches, lakes, or streams. A brief summary of environmental impacts follows.

Water quality impairment: Sediment from construction sites adversely affects water clarity, which reduces sunlight penetration thereby limiting photosynthesis by aquatic plants. In addition, impaired water clarity negatively impacts fish searching for their prey. Sediment-laden runoff also transfers nutrients and other pollutants to downstream lakes and rivers, degrades habitats and spawning areas of aquatic organisms, and increases costs for water treatment.

Loss of flood conveyance and storage: Excess sediment from construction sites fills storm sewers and ditches, detention basins, wetlands, and stream and

river channels. This sediment must be removed to maintain the flow or storage capacity. If not removed, this accumulated sediment worsens drainage and flooding problems and can limit the navigability of river channels. In addition, increased rates of runoff from construction sites can cause local flooding problems.

Degradation of natural areas: Over time, sediment accumulation can lead to the degradation of natural plant communities, such as prairies and wetlands. Sediment accumulation has several negative effects on natural communities. The sediment can bury or suffocate existing plants, smother the native seed bank present, and can act as a medium for the germination of exotic plant seeds that were carried in with the sediment. Many of the exotic species are aggressive (e.g., purple loosestrife, reed canary grass) and can eliminate other more desirable species within a short period of time.

Safety and nuisance problems: Sediment on roadways, conveyed either by direct runoff from construction sites or tracking by construction vehicles, can be a traffic safety hazard. Dust generated from unprotected soil on uncontrolled construction sites is a nuisance for adjacent property owners.

2. Urban Runoff

Urban runoff has been sampled at numerous locations in Illinois and around the country. These data show that urban runoff is contaminated with a number of pollutants, including sediment, heavy metals, petroleum-based hydrocarbons, nutrients, pesticides, chlorides, bacteria, and oxygen-demanding organic matter. It is becoming apparent that pollution in urban runoff is more damaging to many water bodies and ecosystems than pollution from municipal and industrial treatment plants, known as point sources.

Much of the pollutant load is generated from impervious surfaces, particularly roadways and parking lots, and is related to automobile traffic. It is not surprising, therefore, that high density development activities, such as commercial, industrial, and highway projects, generally contribute higher pollutant loads than lower density residential developments. Another important factor controlling the level of pollutant runoff from urban areas is the opportunity for natural vegetative filtering on the site. Unfortunately, most modern developments route runoff from impervious surfaces directly into storm sewers or paved channels which effectively convey the pollutants, without any opportunity for infiltration or filtering, into receiving water bodies.

Water quality impacts of urban runoff have been extensively documented around the country. The following are some common impacts noted in Illinois:

Nutrient enrichment/eutrophication: Pollutant loads of phosphorus and nitrogen in urban runoff are substantially higher than in runoff from undeveloped lands. Most nutrients applied in the urban setting are used on lawns, golf courses and other intensively used and maintained landscapes. Nutrients either

move with the water, like nitrogen, or are attached to eroded soil, like phosphorous. High nutrient levels in lakes and slow moving rivers can result in excessive growth of algae and other aquatic plants which can impair aesthetics, water quality, and recreational potential.

Toxicity to aquatic life: Urban runoff pollutant concentrations often exceed water quality standards. Potential toxicants include pesticides, other organic compounds, and heavy metals. Such toxicants can move with the water, in the air, attached to soil particles, or in plants and animals depending on their solubility in water, origin, mode of application, and other chemical and physical properties. While existing data are not conclusive in showing that these pollutants occur in water bodies in concentrations which are acutely toxic to aquatic biota, there is evidence to indicate that adverse impacts may result from chronic exposure and bioaccumulation of pollutants in the tissue of sensitive organisms. Factors that may worsen toxicity effects include high water temperature (discussed below) and low dissolved oxygen. Dissolved oxygen may be reduced to dangerous levels due to the decomposition of organic matter that is washed off of urban land surfaces by storm events, particularly during the summer time. Low dissolved oxygen also may be a problem during winter ice-cover conditions due to the oxygen demand of contaminated sediments and decaying plant matter. Fish kills are common in urban lakes and detention ponds as a result of such factors.

Sediment contamination: The bottom substrates of water bodies in urban areas are typically coated with a layer of contaminated sediment resulting from urban runoff. This sediment may interfere with the reproduction and feeding mechanisms of aquatic organisms, including fish. It also may be toxic to some sensitive organisms due to elevated concentrations of pesticides, heavy metals, and petroleum-based organic compounds. Urban runoff sediments may also have a relatively high organic content that exerts an oxygen demand as it is "broken down" in receiving water bodies.

Bacterial contamination: The water quality standard for fecal coliform bacteria is frequently violated in urban water bodies following storm events. The violation of this standard generally reflects the presence of significant animal or human waste in the water, and is commonly used as an indicator for the closing of swimming beaches. Additional tests are typically needed to verify whether the contamination is of human origin, such as from faulty septic systems or illicit connections between sanitary sewers and storm sewers.

Salt contamination: The use of salt as a deicing agent can result in extremely high salinity levels in roadside ditches and downstream water bodies. While salinity levels are typically not high enough to be acutely toxic to fish and other aquatic organisms, they may adversely impact sensitive plant communities, particularly wetland species. Further, salt and other soluble urban runoff constituents can degrade aquifers used as a source of water supply.

Impaired aesthetic conditions: Urban runoff carries a number of constituents that may impair the visual appeal and clarity of receiving water bodies. These constituents, including trash and debris, suspended solids, and oil and grease, reduce the recreational potential of many water bodies in urban areas.

Elevated water temperatures: Watershed urbanization has been shown to significantly increase summertime temperatures in receiving streams. This effect is due to a number of factors, including the removal of natural shading and the reduction of base flows, as discussed below. Runoff from impervious surfaces that have been heated by the sun also contributes to this effect. The resultant elevated water temperatures are directly stressful to native aquatic life and increases water quality problems.

Impairment of water supplies: Many of the contaminants listed above adversely affect both surface and groundwater sources of water supply. While surface water impacts can be directly determined from existing data, it is much more difficult to assess the effects to groundwater because of the complexity of multiple sources and routes into underground aquifers.

Beyond their effects on runoff quality, development activities invariably alter runoff patterns by converting pervious land to impervious surfaces and compacting remaining pervious surfaces (e.g., lawns). This conversion results in dramatic increases in the rate and volume of storm runoff and reductions in groundwater recharge. Also, urban drainage features such as storm sewers and lined channels convey runoff water downstream at a much faster rate. This leads to a number of consequences, several of which are explained below.

Increased flooding: Flood flow rates have been shown to increase by 100 to 200 percent or more if a watershed is urbanized without effective stormwater detention. Local drainage problems also are made more severe. As a result, flood damages may be sustained by downstream residences and businesses, and government officials may be forced to implement expensive remedial projects.

Stream channel erosion: Increased rates of runoff and resultant high channel velocities can destabilize downstream channels leading to excessive bank erosion and/or downcutting of the channel, often threatening adjacent structures. This problem is common in Illinois streams, particularly where alterations have been made to the stream or watershed.

Hydrologic destabilization: Development generally results in higher, and more frequent storm flows, and lower and longer duration low flows. The more frequent high flows and the high velocities that accompany them can sometimes "flush out" natural substrates and bottom dwelling organisms. The lower low flows tend to concentrate stream pollutants and reduce stream depths necessary for the survival of fish. Extended low flows also can result in higher summertime water temperatures that further stress fish and other aquatic organisms.

Reduced recharge rates can also result in lower water levels in lakes and wetlands during critical dry periods.

3. Hydrologic/Habitat Modification

Some urban developments directly impact sensitive water bodies and wetlands. To accommodate development plans, streams are sometimes channelized or rerouted. Wetlands may be filled, excavated, or drained. More subtle forms of modification include the removal of native vegetation from stream banks and lakeshores. These activities not only destroy critical aquatic habitats, they also impair other valuable functions. These impacts are summarized below.

Destruction of aquatic and terrestrial habitat: Draining, straightening, vegetation removal, filling, and dredging of natural water bodies and wetlands adversely affects habitat for water dependent fish, wildlife, and waterfowl. In addition to short-term effects caused by construction, significant long-term effects often result due to the elimination of spawning and breeding areas, cover, shading, and a general reduction in habitat diversity. Often, the result of construction in a water body or wetland is the replacement of native vegetation with man-made structures such as riprap or metal retaining walls. Such man-made structures typically do not address the habitat needs of resident aquatic life and wildlife.

Water quality impairment: Construction in and adjacent to water bodies and wetlands create both long-term and short-term effects on water quality. The primary short-term effect is erosion, which was discussed previously. However, the consequences of construction in water bodies and wetlands are often much more severe than construction in upland locations because of the erosive effects of flowing water and wave action. The long-term effects of development in water bodies and wetlands relate primarily to the elimination of vegetation and other natural materials. The typical consequences of these alterations include reduced shading and a resultant increase in water temperature, reduced capacity for pollutant filtering, and an increased propensity for instability and erosion.

Alteration of natural storage and conveyance functions: While state and federal regulations place some constraints on the degree of alteration allowed in floodplains and wetlands, there may still be significant adverse impacts on natural stormwater storage and conveyance functions. Typical consequences include the reduction in stream roughness (or flow retardance) and length due to channel modifications and loss of stormwater storage due to draining or filling of small wetlands. This results in increased flow velocities and volumes, which cause stream channel erosion and increased flooding.

The ultimate concern regarding non-point sources is whether they impair the desired uses of water bodies and aquatic ecosystems -- particularly aquatic life, swimming, and water supply uses. There now is clear evidence from Illinois and around the country that watershed urbanization has serious adverse impacts on the beneficial uses of

downstream water bodies. In northeastern Illinois, an analysis of data from over forty streams and rivers showed that virtually all streams with urban or suburban watersheds had degraded fish communities (i.e., fair to poor conditions based on the Index of Biotic Integrity). In contrast, nearly all streams in rural/agricultural watersheds had good to excellent fish communities. While this correlation may not apply statewide, it does indicate the need to better control urban non-point source impacts to avoid the otherwise inevitable degradation of receiving water bodies.

B. PLANNING PRINCIPLES FOR SELECTING AND IMPLEMENTING BEST MANAGEMENT PRACTICES

Planning principles are the overall guidelines that need to be considered to develop and implement a non-point source control plan that will survive the test of time and provide ecologically and economically sustainable development, while meeting the needs of society. The basic planning principles listed below apply both to new developments as well as existing sites in need of remedial BMPs.

1. Thoroughly collect, review and understand all existing local, state, federal governmental or agency rules, regulations, restrictions, codes, permits, etc.
2. Determine who can help you develop a plan that meets your needs and addresses identified resource concerns.
3. Thoroughly document the pre-development characteristics of the site and immediate surroundings, focusing particularly on topography, drainage patterns, soils, and the presence of important natural features such as streams, water bodies, wetlands, woodlands, and natural area remnants.
4. Plan the development or remedial project to fit the particular topography, soil, drainage patterns and natural vegetation of the site.

Application of these planning principles is particularly important for new developments. Good site planning is often the key to minimizing adverse environmental impacts. Effective site planning and design will result in minimal impacts to water quality, natural hydrologic characteristics, and sensitive landscape features. Site design and the application of sound planning principles are critical factors in achieving effective soil erosion and sediment control, stormwater management, and protection of stream, lake, and wetland resources as described below.

C. PLANNING PRINCIPLES FOR SOIL EROSION AND SEDIMENT CONTROL

This manual describes BMPs to accomplish three basic elements of erosion and sediment control:

- Soil stabilization;
- Runoff control; and

- Sediment control.

The most important, and most often neglected, task is to provide effective soil stabilization throughout the duration of a construction project. Soil stabilization is based on a simple premise: If water cannot detach the soil, it cannot be transported (i.e., erosion does not occur). The easiest, most economical, and environmentally sound way to prevent detachment is by keeping a good vegetative cover in place. It also can be accomplished via other techniques such as mulching or use of erosion blankets.

Runoff control measures are needed to deal with concentrated runoff. Concentrated runoff is a common occurrence on large sites containing existing drainageways and is made more severe by grading activities that removes water absorbent topsoil and compact underlying soils. If concentrated runoff occurs, it will further erode the soil and carry it into streams, lakes, or road ditches. The basic principles behind runoff control measures are to provide stabilized channels for runoff water and to divert concentrated runoff from exposed, erodible soils.

Once the soil is detached, flowing water transports the soil to downslope positions. Sediment control measures are needed to filter, trap, or otherwise remove eroded sediments before they can leave the construction site.

In implementing the erosion and sediment control BMPs described in this manual, it is important to understand them in the context of an overall construction site plan. The following site design, management, and maintenance principles should be implemented on all construction sites.

1. Plan the development to fit the particular topography, soil, drainage patterns and natural vegetation of the site.
2. Preserve and protect areas of natural vegetation on the site.
3. Take special precautions to prevent damages that could result from development activity adjacent to watercourses, lakes, and wetlands.
4. Minimize the extent and duration of the area exposed at one time.
5. Apply temporary erosion control practices as soon as possible to stabilize exposed soils and prevent on-site damage.
6. Install sediment basins or traps, filter barriers, diversions, and perimeter control practices prior to site clearing and grading to protect the disturbed area from off-site and onsite runoff and to prevent sedimentation damage to areas below the development site.
7. Keep runoff velocities low and retain runoff on the site, as much as possible.
8. Provide measures to prevent sediment from being tracked onto public or private roadways.

9. Implement final grading and install permanent vegetation on disturbed areas as soon as possible.
10. Implement a thorough inspection, maintenance, and follow-up program.

D. PLANNING PRINCIPLES FOR STORMWATER MANAGEMENT

This manual describes BMPs to accomplish two basic elements of stormwater management:

- Drainage control; and
- Detention.

In implementing drainage and detention BMPs, however, it is critical that site design decisions reflect the ultimate goal of effective stormwater management--*to minimize the adverse impacts of stormwater runoff both onsite and offsite*. In other words, stormwater management should be looked at as part of the whole watershed, not just the site being developed.

The philosophy endorsed in this manual is to develop stormwater systems that mimic, as closely as possible, the runoff process of the site in its natural state. This philosophy involves the preservation of natural storage, infiltration, and filtering functions.

The primary objectives of the recommended stormwater management approach are to: 1) minimize water quality degradation; 2) minimize downstream channel erosion and habitat loss; 3) maintain natural base flows and groundwater recharge; 4) prevent increases in downstream flooding; 5) provide opportunities for multiple use of drainage and storage facilities; and 6) provide for economical, safe, aesthetic, and socially acceptable drainage within new developments.

Ideally, stormwater management based on this philosophy will not only preserve beneficial uses of downstream water bodies but also will reduce drainage system construction costs. This is accomplished by minimizing the need for expensive capital improvements to the existing drainage system to convey, store, and treat increased runoff volumes and rates.

In order to achieve these objectives, the following site planning and design principles should be implemented on all developments. These principles constitute what is sometimes called a runoff reduction hierarchy.

1. Plan the development to fit the particular topography, soil, drainage patterns and natural vegetation of the site.
2. Minimize impervious surfaces on the property, consistent with the needs of the project, to maximize infiltration opportunities.
3. Reduce flows by use of open vegetated swales, filter strips, and natural

depressions and preserve existing natural drainageways.

4. Infiltrate runoff on-site, as allowed by local soil conditions.
5. Provide stormwater detention designed to emulate natural wetland and pond systems.
6. Construct storm sewers only on an as-needed basis.

E. PLANNING PRINCIPLES FOR SPECIAL AREA PROTECTION

The final category of BMPs included in this manual deal with the protection and restoration of special areas, including:

- Streambanks and shorelines;
- Wetlands and water bodies;
- Trees and native vegetation (including natural areas);
- Steep slopes; and
- Karst areas.

The objectives of special area protection include the preservation of important recreational and habitat amenities and the restoration of degraded resources to a higher functional level. Ultimately, accomplishing these objectives will require site planners to view natural areas from the perspective of long-term sustainability. Planners and developers also should view protection and restoration of natural areas in terms of their positive impacts on site aesthetics, marketing, property values, and reduced long-term maintenance.

The following site planning and design principles will aid decision-makers in identifying and implementing appropriate BMPs.

1. Plan the development to fit the particular topography, soil, drainage patterns and natural vegetation of the site.
2. Consider the unique characteristics of a site, particularly natural areas, as potential amenities which can enhance the aesthetics, land value, and marketing potential of the development.
3. Avoid, wherever possible, the disturbance of existing natural areas including stream corridors, lakes, wetlands, native woodlands and prairies, steep slopes and karst.
4. Protect the integrity and long-term health of natural areas through the utilization of buffers, setbacks, and cluster development techniques.

5. Where feasible, utilize native vegetation and natural materials in the design of BMPs based on local soil, topographic, and pre-settlement vegetation conditions.

BEST MANAGEMENT PRACTICES

Section 4 of this manual contains standards for best management practices (BMPs). These BMPs address site-specific NPS pollution problems and opportunities. These practices have been listed two ways: alphabetically and grouped to address the three principal topics identified above (soil erosion and sediment control, stormwater management, and special area protection). These listings should be useful for selecting individual practices or grouping practices to protect or enhance the planned site, as well as adjacent or downstream areas.

It also should be noted that while a practice may be listed in a particular topical area, the same practice also may be applicable in another area. For example, the most common application of a level spreader is probably a stormwater management BMP to evenly distribute runoff from an impervious surface onto a filter strip. Level spreaders also may be used to minimize erosion by dispersing concentrated runoff on construction sites or to establish and maintain desired hydrologic conditions in wetlands.

To implement effective site planning and BMP selection one must understand the preceding NPS pollution processes and follow sound planning principles. The Practice Selection Guide in Table 2.1 indicates the relative impacts that individual practices have on specified problems. Planning procedures, as described in Section 3 of this manual, will assist with problem identification and selection of practices or groups of practices. Section 8 of this manual contains evaluation criteria and provides information relative to effectiveness for addressing a broad spectrum of resource concerns, whether soil, water, air, plant, or animal.

Diversion	815	Channel and ridge constructed to collect and divert runoff	2	2	1		1	1		1	1	1				
Diversion Dike	820	Perimeter dike to manage and divert runoff	2	2	1		1	1		1	1	1				
Dust Control	825	Controlling dust on construction sites and roads	1				1						3	1		
Erosion Blanket	830	Preformed organic or inorganic erosion mat	2		1	1				1	1	2	1			
Filter Strip	835	Vegetated filter zone to remove pollutants			2		1			1	1	2				
Grass-Lined Channels	840	Natural or constructed channel vegetated to convey water		2		2		1		1	1	1			1	
Impoundment Structure-Full Flow	841	Structure for collecting and storing water, debris, or sediment		3		3		2	2	2	2	2			2	
Impoundment Structure-Routed	842	Structure for collecting and storing water, debris, or sediment		3		3		3	3	3	3	3			3	
Infiltration Trench	847	Pits or trenches designed to hold water to increase infiltration	1	1				1	1	1	1					
Inlet Protection-Block and Gravel	850	Temporary sediment control barrier at storm drain inlet								1	1	1				
Inlet Protection-Excavated Drain	855	Excavated area to trap sediment at storm drain inlet								1	1	1				
Inlet Protection-Fabric Drop	860	Temporary practice to control sediment at storm drain inlet								1	1	1				
Inlet Protection-Gravel & Wire Mesh	861	Temporary sediment control barrier at storm drain inlet								1	1	1				
Inlet Protection-Sod Filter	862	Sediment filter using sod around a storm drain drop inlet								1	1	1				
Inlet Protection-Straw Bale Barrier	863	Temporary practice to control sediment at storm drain inlet								1	1	1				
Land Grading	865	Smoothing surface to planned grade to improve site	2	2				1		1	1	1		2		
Level Spreader	870	Structure to spread water flow uniformly	1	1	1					1	1	1				
Mulching	875	Placing materials to protect soil surface	2	2	1				1	2	2	2	2			
Permanent Vegetation	880	Establishing permanent vegetative cover	3	3	2		2	2	2	3	3	3	3	1		
Permeable Pavement	890	Pavement having interspersed sod, gravel, or sand areas	1	1				1	1	1	1					
Portable Sediment Tank	895	Container for trapping sediment from runoff water								1	1	2				
Right-of-way Diversion	900	Structure to control roadway erosion		1				1				1		2		
Rock Check Dam	905	Structure to control erosion in ditch or grass swale		3								2				
Rock Outlet Protection	910	Rocked area at outlets to reduce flow erosion		2		2						1				
Silt Fence	920	Temporary sediment barrier of filter fabric	2	2						1	1	2				
Sodding	925	Laying blanket of established turf to protect area	3	3	2		1	2	2	3	3	3	3	1		
Stabilized Construction Entrance	930	Rock pad at entrance or exit to control tracking of mud to streets										1		3		
Straw Bale Barrier	935	Bale barrier to trap sediment from runoff	2	2						1	1	2				
Structural Streambank Stabilization	940	Structure to control streambank erosion			3							2				
Subsurface Drain	945	An underground water collection and transport tube	1	1	2		2	1	2	1	1	1		2	3	
Sump Pit	950	Temporary pit to trap and filter water								2	2	2				
Surface Roughening	953	Grooving, stair stepping, or tracking across a slope	1	1					1			1				
Temporary Diversion	955	Temporary diversion for runoff control	2	2	1		1	1		1	1	1				
Temporary Sediment Trap	960	Temporary ponding basin to trap sediment		1					1	1	1	2				
Temporary Seeding	965	Planting vegetation to protect areas from erosion	3	2	2		2	2	2	2	2	2	2			
Temporary Slope Drain	970	Short term water conveyance down a sloping area		2						1	1	1		1		
Temporary Stream Crossing	975	Short term stream crossing for equipment			1	1								2		
Temporary Swale	980	Temporary excavated drainageway to control runoff		1		1		1		1	1	1				
Topsoiling	981	Adding or replacing quality soil to the surface	2	1			2	1	1	1	1	1				
Tree/Forest Ecosystem Preservation	984	Protecting contiguous stands of trees from construction damage	2	2	2			2	1	3	3	1	2		1	
Tree and Shrub Planting	985	Planting trees and shrubs	3	3	3		2	1	2	3	3	3	3		2	
Tree Protection	990	Protecting individual trees from construction damage	1	1	1			1	1	1	1	1	1		1	
Tree Protection-Augering	991	Protecting individual trees from underground construction damage	1	1	1			1	1	1	1	1	1		1	
Vegetative Streambank Stabilization	995	Vegetation to control streambank erosion			3					1	1	1				
Well Decommissioning	996	Permanent sealing of a water well, boring, or monitoring well								3	3					3

1 = Slight Impact 2 = Moderate Impact 3 = Significant Impact

SECTION 3 – PLANNING PROCEDURES

INTRODUCTION

Selection and design of best management practices (BMPs) must involve more than choosing a practice from a list and installing it on a site. It also involves a planning process which considers the problem to be avoided, or remediated, and also factors in the characteristics of the site. Advance planning should occur first in the development of local ordinances in which local governments identify appropriate BMP requirements for new development. Such advance planning will reduce the burden on developers and facilitate the selection of BMPs.

In the context of remedial projects, however, there typically will be no ordinance or "cookbook" to follow. In this setting, planning becomes even more critical in the selection and design of appropriate BMPs.

Planning involves more than simply managing or treating individual problems or resources. It involves a careful, deliberate, and organized approach that is centered on purpose, problem identification, analysis, evaluation, decision-making, and maintenance.

This section of the manual outlines and explains a procedure to identify problems, needs, and objectives; how to inventory, analyze and evaluate BMP alternatives; and finally, how to select and implement practices based on social, environmental, and economic considerations.

Although this manual was developed primarily to address non-point source (NPS) pollution issues, the use and application of the standards are intended to protect, conserve, and enhance natural resources. If planning is approached in this manner, the human impact on the ecosystem will be minimized and related adverse impacts, such as increased flooding, will be minimized.

The Procedures section will cover the following major issues:

- A. Planning process;
- B. Criteria for BMP selection;
- C. Practices and systems; and
- D. Evaluation and monitoring.

This section was revised in January 1999.

NRCS IL January 1999

SECTION 3 – PLANNING PROCEDURES

All sites being developed will vary in their suitability for different types of development. Knowing the soil type, topography, natural landscape values, drainage area, on and offsite hydrology, flooding potential, and other pertinent data helps identify both beneficial features and potential problems of a site and adjacent areas. Generally, the location of the site has already been determined. What is needed then are the best procedures for identifying and addressing potential or existing problems, or to address established restrictions, ordinances, or regulations to develop a site in a quality manner.

A. Planning Process

The process outlined in this manual is a standard process used by NRCS and others. It is a nine-step process that is fully explained in NRCS's National Planning Procedures Handbook.

The nine steps are outlined below:

1. Identify problems - Identify existing, potential, and perceived natural resource problems, opportunities and concerns, including short-term and long-term issues relating to site resources and offsite impacts. As planning progresses and additional information is gathered, other problems and opportunities may be identified.
2. Determine objectives - Determine how the site will be used, what are the site features, what should be enhanced, and what rules, codes, or restrictions need to be addressed. Develop an understanding of the desired future conditions for the planning area as compared to the existing conditions. This includes the desired resource uses, resource problem reductions, and on-site and off-site ecological protection. Non-point source control processes and planning principles are discussed in Section 2. As resources are inventoried, their interactions analyzed, and alternatives formulated, objectives may need to be reviewed and modified.
3. Inventory resources - Collect appropriate natural resource (soil, water, air, plant, and animal), economic, and social information about the planning area. Also consider impacts offsite, such as water running onto or through the site. Use this information to further define existing and potential problems and opportunities, clarify concerns, and to formulate and evaluate alternatives. Gather information as needed concerning the affected resources, the human considerations, and operation and management.
4. Analyze resource data - Study the resource data and clearly define the natural resource conditions, including limitations to their use and potentials. This step provides the information needed to formulate and evaluate alternatives. The analyses should clearly establish the cause and effect relationships and provide information about existing and future conditions. Qualify and quantify resource use and development impacts. Appendix C "Methods for Estimating Water Quality Impacts of Urban and Suburban Development" contains methods to

estimate the impacts of development.

5. Formulate alternatives - Develop alternatives that will achieve the objectives, solve the identified problems, take advantage of opportunities, and prevent additional problems from occurring. Alternative practices are selected from BMPs in Section 4 and may need to be grouped into systems to address multiple problems. Include measures that mitigate potential adverse impacts on the resources and address regulatory requirements.
6. Evaluate alternatives - Evaluate the alternatives to determine their effectiveness in addressing the problems, opportunities and objectives. Alternatives should pass the tests of feasibility and acceptability -- socially, economically and environmentally - or adjustments should be made.
7. Make decisions - The decision-maker determines which alternative(s) to implement and the necessary documentation is prepared. Public review and comment are obtained, if needed, before a decision is reached. Alternatives chosen are in compliance with all applicable regulations.
8. Implement plan - Implementing the plan includes installing BMPs and obtaining necessary permits, funding, land rights, surveys, final designs, and inspections. It also includes the operation, maintenance, and management needed to assure proper functioning of practices following installation. Practices are implemented per the site plan to achieve short term and long term objectives and goals.
9. Evaluate plan - Evaluate the effectiveness of the implemented plan to ensure that it is functioning as planned and achieving the objectives; to identify reasons for lack of progress in plan implementation, if applicable; and to obtain information on the applied treatment. Where the actual results differ from those anticipated, provide feedback into the planning process. This could include revision of quality criteria; modification of indicators/target values; changes to current practice standards; and revision of other Urban Manual data.

The outlined procedure works best if certain pre-planning activities have occurred. Some of these activities include:

1. Define the site planning area on a map.
2. Order or prepare needed work maps and determine map bases and scales.
3. Determine planning objectives and needs, particularly how they relate to ordinances, regulations, and restrictions relating to site development and use.
4. Assemble existing information and data on soil, water, air, plant, and animal resources on and around the site.
5. Determine who needs to be involved in the planning and review processes.

6. Consider data needs for the site.
7. Prepare a draft work plan that identifies action items, responsible parties, and deadlines.

Good pre-planning will expedite and improve the planning process.

B. Criteria for BMP Selection

Once problems or issues are identified, it becomes paramount to establish goals for BMP selection. Many of the goals are established as part of local, state, or federal laws or as part of existing ordinances and codes. The development of the plan and nature and extent of treatment will be guided by these goals.

Section 2 of this manual identifies non-point source impacts and describes the principles for controlling these impacts with the practices contained in Section 4. Section 8 provides guidance for evaluating the relative impact that individual practices have on identified problems and other soil, water, air, plant and animal resources. This should be used to guide decisions on the best practice or combination of practices that solve the identified or potential problems without creating new problems.

The NRCS, along with others, have established treatment levels that correspond with soil, water, air, plant, and animal resource concerns. These standards are established in the NRCS's Field Office Technical Guide, Section 3.

C. Practices and Systems

The core of this manual is the BMP standards, construction specifications, material specifications, and standard drawings which are contained in Sections 4, 5, 6 and 7, respectively. These sections are meant to be dynamic and expandable. As new information becomes available, and field experience evolves, updates and additions will be prepared as determined by the agencies supporting the manual.

However, updates and additions will also depend on the needs of units of government and other users. As users, you can guide the nature of changes by personal contact with the agencies involved in preparation of the manual. Practices not currently provided in this manual may be obtained from several of the other sources identified in the reference section. Additional practice standards and related materials will be developed as needs indicate.

Users must understand that typically several practices will be needed to meet established criteria for addressing any given problem or resource concern. When a combination of practices is evaluated together, it is termed a system, or *treatment train*. A system is often needed to fully address any problem or concern. If there are multiple issues to plan treatment for, the complexity of the system may require additional practices. The development of the appropriate system involves the analysis of the following items:

1. Nature and extent of problem(s)
2. Onsite versus offsite considerations
3. Short term versus long term solutions
4. Treatment requirement standards
5. Long term maintenance considerations
6. Economic considerations
7. Regulatory requirements

D. Evaluation and Monitoring

The best practices for addressing key problems and concerns are identified in Table 2.1 in Section 2. A broader evaluation of the practices on a more complete range of problems or issues is contained in Section 8. On any given site these general rankings may be different than indicated. They are meant to provide a relative range of effectiveness and should be used as a guide. Qualified and experienced professionals in the natural resource field should be consulted to adequately assess the impacts of any proposed actions.

Monitoring of BMP effects should accompany plan implementation, where appropriate and feasible. The effects of the practice or system should normally be observable and some of the indicators listed in Section 2 might be used to qualify results. Revisions to plans should always be considered if unexpected problems or changes to use and management occur.

SECTION 4 – PRACTICE STANDARDS

INTRODUCTION

This section contains the best management practice (BMP) standards. Each standard includes the following information:

- Definition
- Purpose
- Conditions where practice applies
- Criteria (including minimum or maximum requirements)
- Considerations
- Plans and specifications
- Operation and maintenance
- References

The standards in this section are filed in alphabetical order by the name of the practice. This also corresponds to the numerical order for practice code number. A list of the practices grouped into categories based on their principal applications is also provided for cross-reference. This listing is grouped as follows:

Soil Erosion and Sediment Control (SE/SC)

- Soil stabilization
- Runoff control
- Sediment control
- Miscellaneous SE/SC

Stormwater Management

- Drainage control
- Detention

Special Area Protection

- Streambanks and shorelines
- Wetlands and water bodies
- Trees and native vegetation (including natural areas)

- Steep slopes
- Karst areas

As indicated previously, however, some standards (e.g., level spreader or filter strip) may be used for multiple applications.

Standards are usually used in groups as a system to solve a particular concern or multiple concerns. Standards should be selected by professional engineers, planners, site designers, or other natural resource specialists and based on the principles described in Section 2, since any particular standard will not work in all cases.

This section was updated in January 1999.

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

URBAN STORMWATER WETLANDS

(acre)
CODE 800

(Source: Native Plant Guide for Streams and Stormwater Facilities in Northeastern Illinois)

DEFINITION

A constructed system of shallow pools that create growing conditions suitable for emergent and riparian wetland plants explicitly designed to lessen the impacts of stormwater quality and quantity in urban areas.

PURPOSE

Stormwater wetlands are designed and installed to maximize pollutant removal and create wetland habitat through the creation of a matrix of water, sediment, plants, and detritus that collectively provides temporary storage of urban stormwater runoff, and removes multiple pollutants from it through a series of complementary physical, chemical, and biological pathways.

CONDITIONS WHERE PRACTICE APPLIES

This practice applies to watersheds in urban or urbanizing landscapes where stormwater quality and quantity control is needed to meet the diverse management objectives of developers

and local governing units. Stormwater wetlands typically are not located within delineated natural wetland areas. Natural wetlands provide critical habitat and ecosystem benefits and are protected under local, state and federal statutes. Stormwater wetlands should also not be confused with created or restored wetlands that are used to mitigate for the loss of natural wetlands under permitting provisions of wetland protection requirements.

CRITERIA

For maximum effectiveness, the following basic design criteria should be followed to achieve the major objectives of the stormwater wetland:

1. Capture and effectively treat the stormwater runoff produced by 90 percent of the storms in the urban watershed by designing a stormwater wetland to meet seven basic sizing criteria:
 - a. Minimum treatment volume to capture and treat an amount equal to 0.5 watershed inch.

- b. Surface area requirement - minimum wetland to watershed ratio:

Shallow Marsh Wetland	2%
Pond/wetlands	1%
Extended Detention - (ED)/wetlands	1%
Pocket wetlands	1%

 Wetland types are defined in Reference 1.
 - c. Depth/Area allocation guidelines are shown in Table 2.
 - d. Treatment/Volume allocation guidelines are shown in Table 2.
 - e. Flow path length - dry weather flow path of 2:1 for length to width ratio.
 - f. Dry weather water balance - determine that inflow and ground water inputs are greater than infiltration and evaporation water losses for all designs except pocket wetlands.
 - g. Extended detention volume - consider extended volume, time, release, clogging protection, and water elevation.
2. Pre-treat the stormwater runoff before it reaches the wetland area to reduce water velocity, trap coarse sediments and associated pollutants. Examples of pre-treatment structures are pre-settling basins and forebays.
 3. Create a diversity of depth zones within the wetland to meet the unique growing requirements of emergent wetland plants.
 4. Establish a diverse and dense wetland plant community in the shortest possible time.
 5. Create a functional pondscape within and around the wetland that augments pollutant removal, creates better wildlife habitat, and promotes a more natural appearance.

6. Reduce the future maintenance burden of the stormwater wetland through preventative management to protect its long-term function.
7. Provide habitat elements that promote greater wildlife and waterfowl use within the wetland and buffer, but avoid undesirable habitat outcomes.
8. Serve as an attractive, yet safe, community amenity for adjacent residents.
9. Reduce or avoid any undesirable secondary environmental impacts produced by the construction or operation of the stormwater wetland.

CONSIDERATIONS

Avoid conflict with natural wetlands wherever possible. Employ design techniques to enhance pollutant removal performance of stormwater wetland systems (Table 1). Establish the plant community by transplanting stock native to the region and/or by utilizing mulch/topsoil from a nearby donor wetland scheduled to be developed. Plan habitat diversity to meet the feeding, breeding/nesting, and cover requirements for a wide range of aquatic, avian, and terrestrial species. Check with state and/or federal agencies that issue permits for wetlands about the regulatory status of stormwater wetlands and needed permits prior to construction.

PLANS AND SPECIFICATIONS

Site suitability should be determined on each site by field observation by a qualified interdisciplinary design team with expertise in stormwater engineering, wetlands, landscaping, and pond construction. Construction specifications should be shown in a site-

specific construction plan or drawing. Design criteria for stormwater wetland designs are shown in Table 3.

OPERATION AND MAINTENANCE

Both initial establishment and future development of a stormwater wetland require active management of the hydrology and vegetation, as it grows in biomass, diversity, and spatial coverage.

The design team must plan for the future operation and maintenance of the stormwater wetland in this stage, with a strong emphasis on the first three years. Maintenance activities must be fully vested with a responsible party through an enforceable maintenance covenant. The covenant should specifically include a projected schedule for inspections and forebay sediment cleanouts, and show evidence that dedicated funding will be available to perform this function.

Inspection Criteria -The stormwater wetland should be inspected twice a year in the first three years after construction, with an annual inspection thereafter. Inspections should be conducted with the as-built and pondscaping plans in hand, and should take specific note of species distribution/survival, sediment accumulation, water elevations, and condition of the outlet. Records should be stored so that the progressive development of the wetland system over time can be tracked.

Sediment Cleanout - Accumulated sediment in the forebay should be cleaned out every 3 to 5 years. Cleanouts are conducted after draining the forebay with the help of a skid loader or backhoe. The preferred disposal

method is on-site land application at a pre-designated spoil area.

Mowing - The maintenance access, maintenance bench and embankment should be mowed once a year to prevent woody growth. All remaining areas can be managed as a wet meadow or forest.

urbst800.doc

TABLE 1
DESIGN TECHNIQUES TO ENHANCE
POLLUTANT REMOVAL PERFORMANCE OF STORMWATER
WETLAND SYSTEMS

1. Increase the Volume of Runoff Treatment
 - Capture greater percentage of annual runoff volume
 - Provide for longer residence time in wetland for most storm events
2. Increase the Surface Area to Volume Ratio
 - Increase the total area of the wetland, or
 - Increase the internal structural complexity of the wetland, by adding complex microtopography and establishing extensive and dense wetland plant cover
3. Increase the Effective Flow Path Through the Wetland
 - Extend distance between the inlet and outlet berms
 - Maximize sinuosity of dry weather flow path with high marsh wedges
 - Create some areas with extremely shallow flow path (i.e., high marsh)
 - Use multiple cells within the wetland system
4. Provide Runoff Pre-Treatment and Energy Dissipation
 - Use forebay or pond cell near inlet, with broad crested weirs to spread flow between cells
5. Utilize Redundant Pollutant Removal Pathways
 - Provide extended detention to keep removal rates reliable during non-growing season, or
 - Utilize permanent pool to increase algal uptake and sedimentation

From Table 7, Schueler, 1992.

TABLE 2
 GUIDELINES FOR THE ALLOCATION
 OF DEPTH ZONES AND TREATMENT VOLUME IN
 STORMWATER WETLAND SYSTEMS

Stormwater Wetland Systems

TARGET ALLOCATIONS	Design No. 1 <u>SHALLOW MARSH</u>	Design No. 2 <u>POND/WETLAND</u>	Design No. 3 <u>ED WETLAND</u>	Design No. 4 <u>POCKET WETLAND</u>
<u>Percent of Surface Area</u>				
Forebay	5	0	5	0
Micropool	5	5	5	0
Deepwater	5	40	0	5
“Low Marsh”	40	25	40	50
“High Marsh”	40	25	40	40
“Semi-wet”	5	5	10	5
<u>Percent of Treatment Volume</u>				
Forebay	10	0	10	0
Micropool	10	10	10	0
Deepwater	10	60	--	20
“Low Marsh”	45	20	20	55
“High Marsh”	25	10	10	25
“Semi-wet”	0	0	50	0

- Deepwater - One to six feet below normal pool (includes forebays, micropools, pool and channel)
- Low Marsh - Six to 18 inches below normal pool
- High Marsh - Zero to six inches below normal pool
- Semi-wet - Zero to two feet above normal pool (includes ED)

Note: The allocations are only general guidelines and will vary according to design and site constraints.

From Table 11, Schueler, 1992.

TABLE 3 - DESIGN CRITERIA FOR STORMWATER WETLAND DESIGNS

DESIGN CRITERIA	Design No. 1 SHALLOW MARSH	Design No. 2 POND/ WETLAND	Design No. 3 ED WETLAND	Design No. 4 POCKET WETLAND
Wetland/Watershed Ratio	.02	.01	.01	.01 (target)
Minimum Drainage Area	25 acre	25 acre	10 acre	1-10 acre
Length to Width (minimum)	1:1	1:1	1:1	1:1 (target)
Extended Detention	No	No	Yes	No
Allocation of Treatment Volume (pool, marsh, ED)	40/60/0	70/30/0	20/30/50	20/80/0
Allocation of Surface Area (deep, low, high)	20/40/40	45/25/30	20/35/45	10/40/50
Cleanout Frequency	2-5 yrs.	10 yrs.	2-5 yrs.	10 yrs.

From Table 16, Schueler, 1992.

CONSTRUCTION ROAD STABILIZATION

(ft.)
CODE 806

(Source: USDA - Natural Resources Conservation Service - Illinois)

DEFINITION

The stabilization of temporary construction access routes, subdivision roads, on-site vehicle transportation routes, and construction parking areas with stone immediately after grading.

PURPOSE

The purpose of this practice is to reduce erosion of temporary roadbeds and parking areas by construction traffic during wet weather.

CONDITIONS WHERE PRACTICE APPLIES

Wherever stone base roads or parking areas are constructed for use by construction traffic.

CRITERIA

Construction roads shall follow the contour of the natural terrain to the extent possible. The maximum grade is 10%.

Locate parking areas on naturally flat areas if they are available to minimize

grading. Keep grades sufficient for drainage but not more than 4 %.

Construction roads shall be at least 14 feet wide for one-way traffic and 20 feet wide for two-way traffic. Two-way traffic widths shall be increased a minimum of 4 feet for trailer traffic. The type of vehicle or equipment, speed, loads, climatic and other conditions under which vehicles and equipment are expected to operate need to be considered and the minimum widths increased accordingly.

All cut and fill slopes shall be 2:1 (horizontal to vertical) or flatter.

Roadside ditches shall be provided as needed and shall be designed and constructed in accordance with practice standard [GRASSED LINED CHANNEL 840](#).

The roadbed or parking surface shall be cleared of all vegetation, roots and other objectionable material.

Where seepage areas or seasonally wet areas must be crossed, install subsurface drains and geotextile filter

fabric. Subsurface drains shall be installed in accordance with practice standard [SUBSURFACE DRAIN 945](#). Geotextile filter fabric, which is used to minimize the migration of stone into the underlying soil by heavy vehicle loads, shall meet the requirements of material specification [592 GEOTEXTILE](#) Table 1 or 2, Class I, II or IV.

At a minimum a 6 inch course of coarse aggregate meeting IDOT CA-1, CA-2, CA-3 or CA-4 gradation shall be applied immediately after grading or the completion of utility installation within the right-of-way.

All roadside ditches, cuts, fills, and disturbed areas adjacent to parking areas shall be stabilized in accordance with practice standards [PERMANENT VEGETATION 880](#) or [TEMPORARY SEEDING 965](#), as applicable.

CONSIDERATIONS

Improperly planned and maintained roads can become a continual erosion problem. Excess runoff from roads cause erosion in adjacent areas, and an unstabilized road may become a dust problem. Construction vehicle traffic routes are especially susceptible to erosion because they become compacted and collect and convey runoff along their surfaces. Rills, gullies and troublesome muddy areas form unless the road is stabilized.

During wet weather, unstabilized dirt roads may become so muddy they are virtually unusable, generating sediment and causing work interruption. Proper grading and stabilization of construction routes often saves money for the contractor by improving the overall

efficiency of the construction operation while reducing the erosion problem.

Low-grade asphalt or asphalt grindings may be used to facilitate maintenance and removal of tracked earth.

Filter fabric may be used under the coarse aggregate to provide a stable foundation and to facilitate removal of the stone.

PLANS AND SPECIFICATIONS

Plans and specifications for installing construction road stabilization shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following:

1. Location where the practice will be installed
2. Dimensions of the practice - length, width and thickness
3. Alignment and grade of the practice
4. Type of materials

All plans shall include installation, inspection, and maintenance schedules with the responsible party identified.

Standard drawing [CONSTRUCTION ROAD STABILIZATION IL-506](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

Inspect the condition of the surface of construction roads and parking areas. Construction roads quickly accumulate a layer of earth tracked by vehicular traffic that is a source of airborne dust. Periodic blading of the accumulated earth and top-dressing with new stone will be necessary.

Inspect seeded areas adjacent to the roads and parking areas to ensure that a vigorous stand of vegetation is maintained and inspect roadside ditches and other drainage structures to ensure that they do not become clogged with silt or other debris.

CULVERT INLET PROTECTION

(no.)
CODE 808

(Source: USDA Natural Resources Conservation Service - Illinois)

DEFINITION

A temporary sediment filter located at the inlet to storm sewer culverts.

PURPOSE

The purpose of this practice is to prevent sediment from entering, accumulating in and being transferred by a culvert and associated drainage system prior to permanent stabilization of a disturbed project area.

CONDITIONS WHERE PRACTICE APPLIES

This practice applies where a culvert and associated drainage system are to be made operational prior to the stabilization of the disturbed drainage area.

CRITERIA

All culvert inlet protection shall be constructed in a manner that will facilitate cleanout and disposal of trapped sediment and minimizes interference with construction activities.

All culvert inlet protection shall be constructed in such a manner that any resultant ponding of stormwater will not cause inconvenience or damage to adjacent areas or structures.

Silt Fence Culvert Inlet Protection

This type of culvert inlet protection has an expected maximum usable life of 3 months.

The maximum area draining to this practice shall be 1 acre.

All criteria included in practice standard [SILT FENCE 920](#) shall apply except the maximum spacing between the posts shall be 3 feet and tops of posts shall be cross-braced.

The placement of the silt fence shall be a minimum of 6 feet from the culvert in the direction of incoming flow, creating a "horseshoe" shape.

If the drainage area exceeds 1 acre, or flow and/or velocity of the flow to the culvert inlet protection is excessive and may breach the structure, use the Stone Culvert Inlet Protection criteria.

Stone Culvert Inlet Protection

Stone culvert inlet protection has a maximum expected useful life of 18 months.

The maximum area draining to this practice shall be 3 acres. For drainage areas larger than 3 acres install a temporary sediment trap meeting the requirements of practice standard [TEMPORARY SEDIMENT TRAP 960](#).

The stone culvert inlet protection is a small stone berm in a horseshoe shape around the culvert inlet. The upstream half of the stone berm shall consist of coarse aggregate meeting IDOT CA-1, CA-2, CA-3 or CA-4 gradation and the downstream half of the stone berm shall consist of riprap meeting IDOT RR-3 or RR-4 gradation. In addition, any riprap that is used for permanent protection on the culvert inlet embankment shall meet IDOT Quality Designation A.

The downstream toe of the stone berm shall be no closer than 24 inches from the culvert opening in order to provide an acceptable emergency outlet for flows from larger storm events.

Maximum height of the stone berm shall be 3 feet.

Side slopes of the stone berm section shall not exceed 2:1 horizontal to vertical.

The stone berm shall be tied into the culvert embankment a minimum of 1 foot above the design elevation of the stone berm.

CONSIDERATIONS

When construction on a project reaches a stage where culverts and other storm

sewer appurtenances are installed and many areas are brought to a desired grade, the erosion control measures used in the early stages normally need to be modified or may need to be removed altogether. At that time, there is a need to provide protection at the points where runoff will leave the area via culverts and drop or curb inlets.

Similar to drop and curb inlets, culverts that are made operational prior to the stabilization of the associated drainage areas can convey large amounts of sediment to drainageways or water bodies. In cases of extreme sediment loading, the pipe or pipe system itself may clog or lose a major portion of its capacity. To avoid these problems it is necessary to prevent sediment from entering the culvert by using one of the culvert inlet protection types identified in this standard.

Filter fabric may be used under the stone to provide a stable foundation and to facilitate removal of the stone.

Other protection strategies should be used if this practice has hydraulic impacts off of the subject property.

PLANS AND SPECIFICATIONS

Plans and specifications for installing culvert inlet protection shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. As a minimum include the following:

1. Location where the practice is to be installed
2. Type of culvert inlet protection to be used
3. Type of materials

4. Dimensions and elevations of the practice

NRCS IL January 1999

urbst808.doc

All plans shall include installation, inspection, and maintenance schedules with the responsible party identified.

Standard drawings [IL-508SF CULVERT INLET PROTECTION - SILT FENCE](#) or [IL-508ST CULVERT INLET PROTECTION - STONE](#) may be used as the plan sheet(s).

OPERATION AND MAINTENANCE

The structure shall be inspected after every runoff producing rain and repairs made as needed.

If aggregate is used, it shall be replaced or cleaned when inspection reveals that clogged voids are causing ponding problems.

Sediment shall be removed and the impoundment restored to its original dimensions when sediment has accumulated to one-half the height of the fence or stone berm.

Removed sediment shall be deposited in a suitable area and in such a manner that it will not erode and cause sedimentation problems.

Temporary structures shall be removed when they have served their useful purpose, but not before the upslope area has been permanently stabilized.

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

DIVERSION

(ft.)

CODE 815

(Source: NC Erosion and Sediment Control Field Manual)

DEFINITION

A channel and supporting ridge constructed across the slope to collect and divert runoff.

PURPOSE

The purpose of this practice is to divert excess surface water from one area for use or safe disposal in other areas.

CONDITIONS WHERE PRACTICE APPLIES

This permanent site development practice applies to areas where runoff can be diverted and used or disposed of safely to prevent flood damage, erosion, or sedimentation damage.

Specific locations and conditions include:

1. Above steep slopes to limit surface runoff onto the slope;
2. Across long slopes to reduce slope length to prevent gully erosion;

3. Below steep grades where flooding, seepage problems, or sediment depositions may occur;
4. Around buildings or areas that are subject to damage from runoff.

CRITERIA

Capacity - Diversions designed to protect areas such as minor buildings and roads, shall have enough capacity to carry the peak runoff expected from a storm frequency consistent with the hazard involved but not less than a 25-year frequency, 24-hour duration storm. Diversions designed to protect major structures, homes, school buildings and high capacity roads shall have enough capacity to carry the peak runoff from a 100-year frequency 24-hour duration storm.

Cross-section - The channel may be parabolic, V-shaped, or trapezoidal, and shall accommodate the equipment to be used for maintaining the diversion. The diversion shall be designed to have stable side slopes. Channel cut slopes shall not be steeper than 3:1. The slope

of a vegetated fill shall be 2:1 or flatter. The ridge height shall include an adequate settlement factor. Settlement allowance shall be 10% of design fill height or 0.2 feet, whichever is greater. The ridge shall have a minimum top width of 4 feet at the design elevation. In the case of diversions with a ridge, the design height of the ridge shall be 0.5 feet above the design water elevation. In the case of an excavated channel diversion, the lowest bank of the channel shall be 0.3 feet above the design water elevation. The minimum cross section shall meet the specified dimensions. The top of the constructed ridge shall not be lower than the design elevation plus the specified overfill for settlement.

Grade and velocity - Channel grades may be uniform or variable. Channel velocity shall not exceed that considered erosive for the soil and planned vegetation or lining. See table 1 for the maximum design velocities. Channel grades shall be sufficient to minimize standing water and wetness problems. If possible velocities 2 fps or higher should be used to avoid sedimentation. Compute velocity for bare earth channels using Manning's formula with "n" value of 0.035.

Location - The location of a diversion and outlet shall be in compliance with state drainage law, traditional case law precedent and local ordinances and regulations. Diversion location shall be dictated by outlet condition, topography, land use, length of slope, and soil type. Diversions shall not outlet on the right-of-way of a public road, highway, or other public utility without the written approval of the appropriate authorities.

Sedimentation - Diversions should not be used below high sediment producing areas unless land treatment practices or structural measures, designed to prevent damaging accumulations of sediment in the channels, are installed with or before the diversions. If movement of sediment into the channel is a significant problem, a vegetated filter strip meeting the requirements of practice standard [FILTER STRIP 835](#) shall be used where soil or climate does not preclude its use. Then, the design shall include extra capacity for sediment and be supported by supplemental structures, cultural or tillage practices, or special maintenance measures.

Outlets - Each diversion must have a safe and stable outlet with adequate capacity. Examples of acceptable outlets include but are not limited to [GRASS LINED CHANNELS 840](#), [IMPOUNDMENT STRUCTURE - FULL FLOW 841](#), [IMPOUNDMENT STRUCTURE - ROUTED 842](#), [INFILTRATION TRENCH 847](#), [LEVEL SPREADER 870](#), and [ROCK OUTLET PROTECTION 910](#). The outlet must convey runoff to a point where outflow will not cause damage. Vegetative outlets shall be installed prior to and have vegetation adequately established in the outlet channel before diversion construction. Underground outlets consist of an inlet and underground conduit. Underground outlets shall meet the requirements of the practice standard [SUBSURFACE DRAIN 945](#). The release rate when combined with storage is to be such that the design storm will not overtop the diversion ridge. On large watersheds, runoff flows are usually too large to outlet entirely through underground outlets.

The design elevation of the water surface in the diversion shall not be lower than the design elevation of the water surface in the outlet at their junction when both are operating at design flow.

Vegetation - Disturbed areas shall be established to vegetation as soon as practicable, generally within 15 days after construction is complete. If the soils or climatic conditions preclude the use of vegetation for erosion protection, non-vegetative linings such as gravel, rock riprap, or cellular block may be used. Seedbed preparation, seeding, fertilizing, and mulching shall comply with the practice standards [PERMANENT VEGETATION 880](#) and [MULCHING 875](#). The vegetation shall be maintained and trees and shrubs controlled by hand, machine, or chemicals.

Sediment-laden water should first be directed through an approved sediment-trapping device before entering receiving surface waters. Examples of acceptable sediment trapping facilities include but are not limited to practice standards [IMPOUNDMENT STRUCTURE - ROUTED 842](#) and [TEMPORARY SEDIMENT TRAP 960](#).

CONSIDERATIONS

Diversions should be planned as a part of initial site development. They are principally runoff control measures that subdivide the site into specific drainage areas. Permanent diversions can be installed as temporary diversions until the site is stabilized, then completed as a permanent measure, or they can be installed in final form during the initial construction operation. The amount of sediment anticipated and the

maintenance required as a result of construction operations will determine which approach should be used. Stabilize permanent diversions with vegetation or materials such as riprap, paving stone, or concrete as soon as possible after installation. Base the location, type of stabilization, and diversion configuration on final site conditions. Evaluate function, need, velocity control, outlet stability, and site aesthetics. When properly located, landforms such as landscape islands, swales or ridges can be used effectively as permanent diversions. Base the capacity of a diversion on the runoff characteristics of the site and the potential damage after development. Consider designing an emergency overflow section or bypass area to limit damage from storms that exceed the design storm. The overflow section may be designed as a weir with riprap protection.

A typical diversion cross-section consists of a channel and a supporting ridge. In the case of an excavated type diversion, the natural ground serves as the diversion ridge. Diversion cross sections must be adapted to the equipment that will be used for their construction and maintenance. The channel may be natural, parabolic or trapezoidal in shape; use of "V" channels is generally discouraged due to erosion problems experienced.

At all points where diversion ridges or channels will be crossed by construction equipment, the diversion should be protected according to requirements of the practice standard [STABILIZED CONSTRUCTION ENTRANCE 930](#). Bridges or culverts of adequate capacity may also be used.

Subsurface drainage should be used along permanent vegetated diversion channels when adequate grade can not be achieved to prevent ponding water, when hillside seeps or soils with poor internal drainage keep the channel wet or when base flow is intercepted by the diversion.

every major rainfall and any needed repairs made promptly.

NRCS IL March 1994

urbst815.doc

PLANS AND SPECIFICATIONS

Plans and specifications for installing diversions shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended function. At a minimum include the following items:

1. Diversion location.
2. Channel grade.
3. Diversion cross-sections.
4. Seeding and fertility rates.

All plans shall include the installation, inspection, and maintenance schedules with the responsible party identified.

Construction of the diversion shall meet the requirements as listed in the construction specification [27 DIVERSIONS AND WATERWAYS](#). Standard drawing [IL-515 DIVERSION PLAN](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

A maintenance program shall be established to maintain diversion capacity, storage, ridge height, vegetation and outlet. Maintenance needs are to be discussed with the landowner or operator who is responsible for maintaining the practice. Diversion ridges can be hazardous for mowing. Any hazards must be brought to the attention of the responsible party. Diversions should be inspected after

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

DIVERSION DIKE

(ft.)
CODE 820

(Source: NC Erosion and Sediment Control Planning and Design Manual)

DEFINITION

A dike or dike and channel constructed along the perimeter of a disturbed construction area.

PURPOSE

The purpose of this practice is to prevent storm runoff from entering the work area or to prevent sediment-laden runoff from entering the construction site without first passing through a sediment trapping facility.

CONDITION WHERE PRACTICE APPLIES

Diversion dikes may be located at the upslope side of a construction site to prevent surface runoff from entering the disturbed area or at the downslope side of the work area to divert sediment-laden runoff to on-site sediment traps or basins. Diversion dikes do not usually encircle the entire area.

CRITERIA

Diversion dikes with 3 acres drainage area or less shall be designed using the practice standard [TEMPORARY DIVERSION 955](#). Diversion dikes with drainage areas greater than 3 acres shall be designed using the practice standard [DIVERSION 815](#).

CONSIDERATIONS

A diversion dike is a special application of a temporary or permanent diversion. It differs from other diversions in that the location and grade are usually fixed, and the cross section and stabilization requirements are based on the existing grade of the work boundary. Hence, the design cross section may vary significantly throughout the length. Give special care to avoid erosive velocities in steep areas. Identify areas where sedimentation will occur since they are often subject to overtopping.

Diversion dikes should be protected from damage from ongoing construction activities. At all points where diversion

ridges or channels will be crossed by construction equipment, the diversion should be protected according to requirements of the practice standard [STABILIZED CONSTRUCTION ENTRANCE 930](#). Bridges or culverts of adequate capacity may also be used.

Immediately vegetate diversion dikes after construction, but make sure channel flow area is stabilized during the initial phase of construction. Exercise caution in diverting flow to be certain that the diverted water is released through a stable outlet and that the flow will not cause flood damage. Sediment laden water should first be directed through an approved sediment-trapping device before entering receiving surface waters. Examples of acceptable sediment trapping devices include but are not limited to practice standards [IMPOUNDMENT STRUCTURE-ROUTED 842](#), or [TEMPORARY SEDIMENT TRAP 960](#).

PLANS AND SPECIFICATIONS

The plans and specifications for installing diversion dikes shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

1. Diversion dike location.
2. Minimum cross-sections.
3. Channel grade.
4. Seeding requirements.

All plans shall include the installation, inspection, and maintenance schedules with the responsible party identified.

The diversion dike shall be constructed according to the requirements shown in

construction specification [27 DIVERSIONS AND WATERWAYS](#). Standard drawing [IL-515 DIVERSION PLAN](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

Inspect diversion dikes once a week and after every rainfall. Immediately remove sediment from the flow area and repair the dike. Protect the diversion dike from construction equipment crossing.

A maintenance program shall be established to maintain diversion dike capacity, storage, ridge height, vegetation and outlet. Maintenance needs are to be discussed with the landowner or operator who is responsible for maintaining the practice. Diversion dike ridges can be hazardous for mowing. Any hazards must be brought to the attention of the responsible party.

NRCS IL February 1994

urbst820.doc

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

DUST CONTROL

(acre)
CODE 825

(Source: NC Erosion and Sediment Control Planning and Design Manual)

DEFINITION

Control of dust blowing and movement on construction sites and roads.

PURPOSE

The purposes of this practice are to prevent blowing and movement of dust from exposed soil surfaces, to reduce on and off-site damage, to minimize health hazards, and to improve traffic safety.

CONDITIONS WHERE PRACTICE APPLIES

This practice is applicable to areas subject to dust blowing and movement where on and off-site damage is likely without treatment.

CRITERIA

The following are temporary and permanent methods for dust control.

Temporary Methods:

1. Mulches - See practice standard [MULCHING 875](#). Chemical or wood cellulose fiber binders may be used instead of asphalt to bind mulch material.
2. Vegetative Cover - See practice standard [TEMPORARY SEEDING 965](#).
3. Spray-on Adhesives - These may be used on mineral soils. They are not effective on muck soils. Keep traffic off these areas after application.
 - a. Anionic asphalt emulsion: water dilution - 7:1, coarse spray, 1,200 gal/acre.
 - b. Latex emulsion: water dilution - 12.5:1, fine spray, 235 gal/acre.
 - c. Resin-in-water emulsion: water dilution - 4:1, fine spray, 300 gal/acre.
4. Tillage - Roughen the surface and bring clods to the surface. This is an emergency measure that should be used before soil blowing starts. Begin tillage on windward side of site. Chisel plows with shanks spaced about 12"-18" apart and

spring-toothed harrows are examples of equipment that may produce the desired effect.

5. Irrigation - This is commonly used and affords fast protection for haul roads and other heavy traffic roads. The site is sprinkled with water until the surface is moist. Repeat as needed.
6. Barriers - Solid board fences, snow fences, burlap fences, crate walls, bales of hay and similar material can be used to control air currents and blowing soil. Barriers placed at right angles to prevailing wind currents at intervals of about 10 times their height are effective in controlling soil blowing.
7. Calcium Chloride - Apply at a rate that will keep the surface moist. This chemical may be applied by a mechanical spreader as loose, dry granules or flakes at a rate that keeps the surface moist but not so much as to cause water pollution or plant damage. Application rates should be strictly in accordance with the manufacturer's specified rates. Periodic re-treatment may be needed.
8. Stone - Stone can be used to stabilize roads or other areas during construction using crushed stone or coarse gravel. See practice standard [STABILIZED CONSTRUCTION ENTRANCE 930](#).
9. Street Cleaning - Paved areas that have soil on them from construction sites should be cleaned daily, or as needed, utilizing a street sweeper or bucket-type endloader or scraper.

Permanent Method:

Permanent Vegetation - See the practice standard [PERMANENT VEGETATION 880](#) or [SODDING 925](#).

Existing trees or large shrubs may afford valuable protection if left in place.

CONSIDERATIONS

The easiest way to control dust is to avoid exposed soil surfaces. This is not possible on most construction sites, but the area exposed can usually be reduced by careful planning of controlled traffic patterns and by phasing of clearing and grading operations. Consider use of undisturbed vegetative buffers (min. 50 ft.) between graded areas and protected areas.

PLANS AND SPECIFICATIONS

Plans and specifications for dust control shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum the following items should be included:

1. The area to be treated.
2. The methods that are acceptable to use.

Specifications should indicate when dust control is needed and the method of control to be used. Appropriate industry standards should be used.

All plans shall include the installation, inspection, and maintenance schedules with the responsible party identified.

OPERATION AND MAINTENANCE

When temporary dust control measures are used, repetitive treatment should be applied as needed to accomplish control.

NRCS IL February 1994

urbst825.doc

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

EROSION BLANKET

(sq. ft.)
CODE 830

(Source: USDA - Natural Resources Conservation Service - Illinois)

DEFINITION

A preformed protective blanket of straw or other plant residue, or plastic fibers formed into a mat, usually with a plastic mesh on one or both sides.

PURPOSE

The purposes of this practice are to protect the soil surface from raindrop impacts and overland flow during the establishment of grass or other vegetation, and to reduce soil moisture loss due to evaporation.

CONDITIONS WHERE PRACTICE APPLIES

This practice applies where the protection of newly seeded areas is critical. This is especially important where flowing water may occur before the grass is established. The most common application for erosion control blankets is in the bottom of small channels and on steep embankments.

CRITERIA

Erosion blankets shall be installed after all topsoiling, fertilizing, liming and seeding is complete.

The blanket shall be in firm contact with the soil. It shall be anchored per the manufacturer's recommendation with the proper number and spacing of wire staples. The staples shall be the proper width and length to meet the manufacturer's recommendations.

On slopes and in small drains the blanket shall be unrolled upstream to downstream parallel to the direction of flow. The upstream end of each blanket shall be anchored in a minimum 6-inch deep anchor trench. These blankets, when laid side by side, shall overlap a minimum of 4 inches. When more than one blanket length is needed, the material shall be overlapped 12 inches over the downstream piece. All edges shall be stapled as per manufacturer's recommendation.

CONSIDERATIONS

Erosion blankets will be located as part of the site development plan. They will protect the ground surface from raindrop impacts and flowing water. They will also retain moisture on seeded areas thus increasing the potential for germination and survival of the vegetation. Erosion blankets materials will break down over time. They should be chosen so that they last long enough for the grass or other vegetation to become established.

the blanket then reseeding may be needed. Any erosion blankets that have been displaced will need to be put back and restapled.

NRCS IL August 1994

urbst830.doc

PLANS AND SPECIFICATIONS

Plans and specifications for installing erosion blankets shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

1. Location of the erosion blanket.
2. Type of blanket.
3. Location and cross section of anchor trenches.

All plans shall include the installation, inspection, and maintenance schedules with the responsible party identified.

Standard drawing [EROSION BLANKET PLAN IL-530](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

Inspect all erosion blankets periodically and after rainstorms to check for damage due to water running under the blanket or if the blankets that have been displaced. Where water has flowed under the blanket, more staples may be needed per given area or more frequent anchoring trenches installed. If significant erosion has occurred under

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

FILTER STRIP

(acre)
CODE 835

(Source: USDA - Natural Resources Conservation Service - Illinois)

DEFINITION

A created or preserved area of vegetation designed to remove sediment and other pollutants and to enhance the infiltration of surface water runoff.

PURPOSE

The principal purpose of this practice is to remove sediment and other pollutants from runoff water by filtration, deposition, infiltration, absorption, and vegetative uptake. Another purpose is to reduce runoff quantities from impervious surfaces by infiltrating it into the ground.

CONDITIONS WHERE PRACTICE APPLIES

This practice may be applied in a variety of urban land uses where surface water runoff is discharged as overland sheet flow. Some typical locations of vegetated filter strips include:

1. Adjacent to roadways, parking lots, and other impervious surfaces to

filter and convey runoff before it is discharged to swales, storm sewers, or surface water bodies

2. Lawns where roof downspouts are discharged to disperse and infiltrate runoff
3. Adjacent to wetlands, streams, ponds or lakes, or conservation practices to provide the runoff mitigation benefits described above and to serve as a wildlife habitat buffer
4. On construction sites and land undergoing development to filter sediment from overland sheet flow

CRITERIA

The maximum drainage area to a filter strip shall be 5 acres.

Vegetative filter strips shall have slopes 15% or less.

The minimum length (dimension parallel to flow path) of the filter strip is determined by the drainage area being treated and the width of the filter strip. The filter strip length shall be at least 1/2 the unit area length. The unit area

length is calculated by dividing the drainage area to the filter strip, in square feet, by the filter strip width (dimension perpendicular to flow path), in feet. The minimum filter strip length shall be 5 feet except on construction sites where the minimum length shall be 25 feet.

The width (dimension perpendicular to flow path) of the filter strip determines the required length of the filter strip. The wider the filter strip, the shorter the required filter strip length. The width shall be as near the same width as the impervious area being treated.

Some applications (e.g., roof downspouts) may require a level spreader to prevent a concentrated flow path through the filter strip. Level spreaders shall be installed according to the requirements in practice standard [LEVEL SPREADER 870](#). For parking lots and roadways, a level spreader will not be needed if the edge of the contributing runoff area is reasonably level and uniform. Level spreaders shall be installed in the filter strip every 50 feet of filter strip length on slopes greater than 5% and every 100 feet of filter strip length on slopes 5% or less.

The maximum flow velocity through the filter strip shall be calculated for the 10-year frequency, 24-hour duration storm event and shall not exceed the maximum permissible velocities as described in practice standard [GRASSED LINED CHANNEL 840](#).

Vegetation shall follow the requirements of practice standard [PERMANENT VEGETATION 880](#) and be protected with an erosion control blanket meeting the requirements of practice standard [EROSION BLANKET 830](#) or mulched meeting the requirements of practice

standard [MULCHING 875](#). In place of permanent seeding, the filter strip may be vegetated with sod following the requirements of practice standard [SODDING 925](#).

The filter strip vegetation should be fully established before the contributing impervious surface is created and its runoff directed onto the filter strip. Where this is not possible, the filter strip shall be vegetated with sod.

CONSIDERATIONS

Nearly 80% of the maximum potential settleable solids removal is achieved with the sizing criteria listed above. The efficiency can be increased to nearly 90% if the filter strip length is increased so that it has a length equaling or exceeding the unit area length.

Ideally, filter strips function best on slopes 5% or less. However, on slopes 1 % or less, vegetation used should be tolerant of saturated soil conditions.

It is critical that appropriate soil stabilization materials be applied immediately after seeding on all vegetative filter strips to minimize rill development during cover establishment. Due to the added runoff volumes coming from the impervious surfaces, an erosion control blanket will be necessary in most installations. Mulch may be adequate on relatively flat slopes where the contributing drainage area is small. In addition to stabilizing soils, these materials should significantly aid seed germination and early plant establishment.

Native prairie vegetation should be used if possible. Native vegetation has distinct advantages over turf grass,

including denser, deeper root structure to enhance infiltration; reduced maintenance needs (particularly less need for herbicides and fertilizer); and enhanced wildlife habitat.

If site constraints prevent the installation of broad filter strips meeting the specified sizing criteria, even narrower strips can provide substantial stormwater mitigation benefits in contrast to conventional curb and gutter storm sewer approaches.

Protect the filter strips from heavy foot and vehicular traffic during construction to prevent compaction and loss of infiltration capacity.

The filter strip area should be cleared of trees, stumps, brush, rocks, and similar materials if they are likely to interfere with installation of the filter strip (e.g., cause short-circuiting or concentrations of flow). Ideally, uniform, well vegetated strips of natural/native vegetation should be preserved as filter strips since their infiltration capacities are likely to be greater if grading is avoided.

On construction sites and other areas with bare soil where the filter strip is being used as a temporary sediment control technique, it is critical that temporary stabilization be applied to exposed soils and that concentrated flow through the filter strip be avoided. If the potential for concentrated flow exists, consideration should be given to construction of other sediment control practices above the filter strip. These practices shall meet the requirements of practice standards found in this manual such as practice standard [TEMPORARY SEDIMENT TRAP 960](#), and [SILT FENCE 920](#).

PLANS AND SPECIFICATIONS

Plans and specifications for installing filter strips shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

1. Location of the practice
2. Length and width of the filter strip
3. Slope of the filter strip
4. Required appurtenant practices such as level spreaders or temporary sediment basins
5. Grading requirements, topsoil stockpiling and utilization requirements
6. Soil preparation, seeding and temporary soil stabilization (i.e., erosion control blanket or mulching) requirements

All plans shall include installation, inspection, and maintenance schedules with the responsible party identified.

Standard drawing [FILTER STRIP – GRASSED IL-535](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

On active construction sites, the filter strip shall be inspected after every runoff producing rain and repairs made as needed. After construction, filter strips should be inspected during and after major storm events, particularly during the first one or two years. After the first one or two years, the filter strip may be inspected each spring and after major storm events.

Filter strips should be inspected for proper distribution of flows and signs of erosion. The filter strip should be kept

free of litter. Irrigation needs should be minimal except during extended dry periods. Periodic aeration of the soils may be beneficial if the underlying soils have a high clay content, or there is difficulty in maintaining a good vegetative cover due to compaction.

If erosion is discovered, the eroded areas should be filled, reseeded, and mulched. Then the causes for the erosion should be determined and prevented from recurring.

Maintain the vegetation at the most dense stand possible.

Filter strips vegetated with turf grass should be mowed and the residue harvested a minimum of two or three times a year to promote good growth and vegetative density at ground level, nutrient removal from the system, and filtering ability.

Caution should be used when applying herbicides to filter strips or adjacent areas to minimize pollution to the water resources being protected.

Filter strips vegetated with native species should be managed through prescribed burning once every two to three years, after the vegetation is established. Where prescribed burning is not feasible, mowing may be substituted. In contrast to turf grass, native vegetation should be mowed higher and less frequently.

Filter strips that have accumulated so much sediment that they are higher than adjacent areas should be disked or graded as necessary to reestablish shallow sheet flow conditions, and be reseeded.

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

GRASS-LINED CHANNEL

(acre)
CODE 840

(Source: USDA - Natural Resources Conservation Service - Illinois)

DEFINITION

A natural or constructed channel that is shaped or graded to required dimensions and established with suitable vegetation for stable conveyance of runoff.

PURPOSE

The purpose of this practice is to convey and dispose of concentrated surface runoff without damage from erosion, deposition, or flooding.

CONDITIONS WHERE PRACTICE APPLIES

This practice applies to construction sites and developing areas where:

1. Concentrated runoff will cause damage from erosion or flooding;
2. Sufficient depth of soil materials are present to allow establishment of vegetation that will stabilize the cross section and grade of the channel;
3. Slopes are generally less than 5%;
4. Space is available for a relatively large cross section.

Typical uses include roadside ditches, channels at property boundaries, outlets for diversions, and other channels and drainage of low areas.

CRITERIA

Capacity - As a minimum, grass-lined channels shall carry the peak runoff from the 10-year frequency, 24-hour duration storm. Where flood hazard exists, increase the capacity according to the potential damage. For grass-lined channels with a grade of less than 1 percent, out-of-bank flow may be permitted if such flow will not cause erosion, property or flooding damage. The minimum channel capacity in such cases shall be a 2-year frequency storm. Channel dimensions may be determined by using design tables with appropriate retarding factors or by Manning's formula using an appropriate "n" value. When retarding factors are used, the capacity may be based on "C" retardance and stability on "E" retardance, where the waterway will be regularly mowed and otherwise maintained.

Velocity - The maximum permissible velocities of flow shall not exceed the values shown in Table 1.

Cross section - The channel shape may be parabolic, trapezoidal, or V-shaped, depending on the need and site conditions. The design water surface elevation of a grass-lined channel receiving water from diversions or other tributary channels shall be equal to or less than the design water surface elevation in the diversion or other tributary channels. The parabolic shape is the preferred cross section. The triangular cross-section concentrates flow in the "v" of the channel causing higher and more erosive velocities. When vegetated triangular channels are used, the minimum side slopes should be 6:1 or flatter.

Drainage - Base flow shall be handled by a stone lined center, subsurface drain, or other suitable means since sustained wetness usually prevents adequate vegetative cover. The cross-sectional area of the stone lined center or subsurface drain size to be provided shall accommodate a flow rate of 0.1 cfs/acre or by actual maximum base flow.

Where tile is used along the channel, it should be located as close to 1/3 of the channel (top) width from the center of the waterway as practical. The top of the tile should be at least 2.0 feet (up to 4 feet, where possible) below the bottom of the channel, except where soil or outlet conditions make this depth unpractical. The tile shall meet the requirements shown in the practice standard [SUBSURFACE DRAIN 945](#).

Alignment - Minor changes may be made to improve alignment. Care must

be taken to avoid exposing soil materials (such as sodium soils or high clay content glacial till subsoil) that are not conducive to the establishment and maintenance of adequate vegetative cover.

Outlets - All grass-lined channels shall have a stable outlet with adequate capacity to prevent ponding or flooding damages. Appropriate measures must be taken to dissipate the energy of the flow to prevent scouring of the outlet channel. Examples of acceptable outlets include but are not limited to [GRASS-LINED CHANNELS 840](#), [IMPOUNDMENT STRUCTURE - FULL FLOW 841](#), [IMPOUNDMENT STRUCTURE - ROUTED 842](#), [INFILTRATION TRENCH 847](#), [LEVEL SPREADER 870](#), and [ROCK OUTLET PROTECTION 910](#).

Establishment of vegetation - Grass-lined channels shall be vegetated according to the practice standard [PERMANENT VEGETATION 880](#).

Side slopes - Side slopes shall not be steeper than a ratio of 2 horizontal to 1 vertical. They should be designed to accommodate the equipment used for maintenance. Where planned to be crossed by large equipment, trapezoidal channels shall have side slopes of 8:1 or flatter and be protected according to the practice standard [STABILIZED CONSTRUCTION ENTRANCE 930](#). When triangular (V-shaped) channels are used, the minimum side slopes should be 6:1 or flatter.

Sedimentation protection - Protect permanent grass-lined channels from sediment produced in the watershed, especially during the construction period. This can be accomplished by

the effective use of diversions, sediment traps, protected side inlets and vegetative filter strips along the channel.

Construction - The grass-lined channel will be constructed meeting the requirements of Construction Specification [27 - DIVERSIONS AND WATERWAYS](#).

CONSIDERATIONS

Generally, channels should be located to conform with and use the natural drainage system. Channels may also be needed along development boundaries, roadways, and back lot lines. In all situations channels should be located so that they do not make sharp, unnatural changes in direction or grade of flow. Avoid channels crossing watershed boundaries or ridges.

Major reconfiguration of the drainage system often entails increased maintenance and risk of failure.

Establishment of a dense, erosion resistant vegetation is essential. Construct and vegetate grass-lined channels early in the construction schedule before grading and paving increase the rate of runoff.

All grass-lined channels should be designed to permit easy crossing of equipment during construction and maintenance.

If local ordinances permit, storm sewers may be used to extend existing agricultural tile or base flow across a development. They may also be used as an under drain for the channel if the conduit is open jointed.

Geotextile fabrics or special mulch protection such as fiberglass roving or

straw and netting provide stability until the vegetation is fully established. It may also be necessary to divert water from the channel until vegetation is established or to line the channel with sod. Rock checks or filter fabric checks may also be needed to protect the channel before vegetation is established. Sediment traps may be needed at channel inlets and outlets.

Applicable state drainage laws, traditional case law precedent and local ordinances and regulations must be observed in locating grass-lined channels.

PLANS AND SPECIFICATIONS

Plans and specifications for installing grass-lined channels shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

1. Channel location and alignment.
2. Grade, depth and width.
3. Channel cross section type.
4. Seeding specifications and dates.
5. Subsurface drainage, if needed.

All plans shall include the installation, inspection, and maintenance schedules with the responsible party identified.

The grass-lined channel will be constructed meeting the requirements of Construction Specification [27 DIVERSIONS AND WATERWAYS](#). Standard drawings [WATERWAY PLAN IL-540 P, T, or V](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

During the establishment period, inspect grass-lined channels after every rainfall.

After grass is established, check the channel at regular intervals and after every heavy rainfall event. Immediately make repairs. It is particularly important to check the channel outlet and all road crossings for bank stability and evidence of piping or scour holes. Remove all significant sediment accumulations to maintain the designed carrying capacity. Keep the grass in a healthy, vigorous condition at all times, since it is the primary erosion protection for the channel.

NRCS IL October 2001

urbst840.doc

TABLE 1

PERMISSIBLE VELOCITIES FOR CHANNELS LINED WITH VEGETATION

Channel Slope (%)	Lining	Permissible Velocity (ft./sec.) ^{1/}
0 – 5	Tall fescue	5
	Kentucky bluegrass	
	Smooth bromegrass	
	Grass-legume mixture	4
	Red fescue Redtop	3
	Small grains ^{2/}	2.5
5 – 10	Tall fescue	5
	Kentucky bluegrass Smooth bromegrass	4
	Grass-legume mixture	3
Greater than 10	Tall fescue	3
	Kentucky bluegrass	
	Smooth bromegrass	

^{1/} For highly erodible soils, permissible velocities should be decreased 25%. An erodibility factor (K) greater than 0.35 would indicate a highly erodible soil. Erodibility factors (K-factors) for Illinois soils are available in every NRCS office.

^{2/} For temporary seedings.

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

IMPOUNDMENT STRUCTURE - FULL FLOW

(no.)
CODE 841

(Source: Native Plant Guide for Streams and Stormwater Facilities in Northeastern Illinois)

DEFINITION

A dam or excavation which creates an impoundment to collect and store debris, sediment, or water.

PURPOSE

The purpose of this practice is to reduce sediment and/or debris in runoff waters to prevent damage to downstream facilities; or to provide surface water for consumption, irrigation, wildlife habitat, recreation or fire protection.

CONDITIONS WHERE PRACTICE APPLIES

This practice applies where sediment or debris is expected to be contained in runoff waters and may impair the capacity of the watercourse or damage other structures or where a surface water supply is desirable; where storage for at least one inch of water from the contributing watershed is either impractical or undesirable and where any embankment does not exceed the limits for class III, small dams, as defined by the IDNR-OWR in "Rules for

Construction and Maintenance of Dams" and the landowner or other responsible party has secured necessary permits, if required, for design and construction from IDNR-OWR and any local governmental authorities.

CRITERIA

Investigations - sufficient investigations shall be made of the impoundment site and borrow areas to determine the suitability of site and materials for construction, water holding ability and structure stability. A complete analysis of foundation and proposed fill materials shall be made when, in the opinion of the responsible engineer, it is necessary.

Hazard/safety - structures designed under criteria found in this practice shall fall within the class III, small dam category, defined by the IDNR-OWR as follows: "*class III. Dams located where failure has low probability for causing loss of life, where there are no permanent structures for human habitation, or minimum economic loss in*

excess of that which naturally would occur downstream of the dam if the dam had not failed. A dam has a low probability for causing loss of life or minimal economic loss if it is located where its failure may cause damage to agricultural fields, timber areas, township roads, or similar type areas where people seldom are present and where there are few structures. This corresponds to US Army Corps of Engineers Low Hazard Potential and USDA NRCS class a dams."

Small dams have a total impounding capacity of less than 1000 acre-feet and dam height of less than 40 feet, where dam height is defined as "*height of dam, in feet, as measured from the natural bed of the stream or watercourse at the downstream dam slope toe of the barrier to the top of the embankment or barrier.*"

Owners of impoundment structures shall obtain all necessary permits. IDNR-OWR permits may be required for class III, small dams where:

1. The drainage area of the proposed dam is 6400 acres or more in a rural area or 640 acres or more in an urban area, or
2. The dam is 25 feet or more in height, provided that the impounding capacity is greater than 15 acre-feet, or
3. The dam has an impounding capacity of 50 acre-feet or more provided that the dam height is greater than 6 feet.

Pool capacities - structures for the impoundment of debris or sediment shall have a capacity equal to the volume of sediment or debris expected to be trapped at the site during the planned useful life of the structure. That

capacity may be proportionally reduced, if periodic removal of sediment/debris is planned.

Structures that impound water for consumptive use shall have capacity as required by local consumptive use standards.

Structures that impound water for irrigation, wildlife habitat or recreation shall have capacity and depth adequate for the intended use.

Structures that impound water for fire protection shall have a capacity of at least 4000 cubic feet per residence. That capacity shall exist between the inlet to hydrant and an elevation three feet below the permanent pool elevation.

Runoff computation - total runoff amounts and peak discharges may be computed using procedures found in NRCS Engineering Field Handbook, NRCS National Engineering Handbook, SCS TR-55 and TR-20, US Army Corps of Engineers HEC-1 or other procedures designated by the appropriate regulatory authorities.

Principal spillways - non-permit, IDNR-OWR class III dams shall have a principal spillway structure capable of passing the peak discharge from a 24-hour duration storm event of frequency specified in Table 1 with stage at or below emergency spillway crest.

IDNR-OWR class III, permit size dams shall have a principal spillway structure capable of passing the peak discharge from a 24-hour, 25 year storm event with stage at or below the emergency spillway crest.

Principal spillway structures may be conduits, weir-type straight drops, or chutes.

Principal spillway pipe conduits and fittings may be metal, as per NRCS material specifications 551, 552, or 554 or non-metal, as per NRCS material specifications 541, 542, 544, or 547. Conduits of other materials may be used at the discretion of the appropriate regulatory authorities.

Pipe conduits should meet the following requirements:

The pipe should be capable of withstanding external loading without yielding, buckling, or cracking. Pipe strength should not be less than that of the grades indicated in Table 2 for plastic pipe and in Table 3 for corrugated aluminum and galvanized steel pipe. Flexible pipe strength shall not be less than that necessary to support the design load with maximum 5 percent deflection. The inlets and outlets should be structurally sound and made of materials compatible with that of the pipe. All pipe joints should be made watertight by the use of couplings or gaskets or by welding or caulking.

Acceptable pipe materials are cast-iron, steel, corrugated steel, or aluminum, concrete, plastic, vitrified clay with rubber gaskets, and cast-in-place reinforced concrete. Aluminum pipe will not be used in soils with pH values outside the range of 4-9. Concrete and vitrified clay pipe should be laid in a concrete bedding. Plastic pipe that will be exposed to direct sunlight should be made of ultraviolet-resistant materials and protected by coating or shielding, or provisions for replacement should be specified. Connections of plastic pipe to

less flexible pipe or structures must be designed to avoid stress concentrations that could rupture the plastic. Cantilever outlet sections, if used, should be designed to withstand the cantilever load. Pipe supports should be provided when needed. Other suitable outlet protection structure devices may also be used to provide a safe outlet.

Anti-seep collars should be installed around the pipe conduit in the normal saturation zone if any of the following conditions exist:

1. The settled dam height exceeds 15 feet.
2. The conduit is of smooth exterior pipe larger than eight inches in diameter.
3. The conduit is of corrugated exterior pipe larger than 12 inches in diameter.

Anti-seep collars and their connections to the pipe should be watertight. The collar material should be compatible with pipe materials. The maximum spacing should be approximately 14 times the minimum projection of the collar measured perpendicular to the pipe. A minimum of one anti-seep collar should be used on all conduits.

Closed conduit spillways designed for pressure flow must have adequate anti-vortex devices at their inlets.

If needed to prevent clogging of the conduit, an appropriate trash guard should be installed at the inlet or riser.

For safety reasons, all vertical drop inlets should be constructed to prevent accidental injury. This may be accomplished by using a horizontal anti-vortex baffle, trash rack or guardrail.

Procedures for designing, dimensioning, and detailing pipe conduit spillways may be found in the NRCS Engineering Field Handbook, the NRCS National Engineering Handbook and Illinois Procedures and Standards for Urban Soil Erosion and Sedimentation Control or other references specified by local regulatory authorities.

Weir-type straight drops or box inlets and chutes shall be designed according to procedures in the NRCS Engineering Field Handbook, the NRCS National Engineering Handbook, and the USDA Agricultural Handbook No. 301, or as specified by the local regulatory authorities.

NRCS toe wall drop structures can be used if the vertical drop is 4 feet or less, flows are intermittent, downstream grades are stable, and tailwater depth at design flow is equal to or greater than one-third of the height of the overfall.

The ratio of the capacity of drop boxes to road culverts shall be as required by the responsible road authority. The drop box capacity attached to a new or existing culvert must equal or exceed the culvert capacity at the design flow.

Emergency spillways - An emergency spillway must be provided for each dam, unless the principal spillway is large enough to pass peak discharge from the routed design hydrograph and the trash that comes to it without overtopping the dam. The following are minimum criteria for acceptable use of pipe conduit principal spillway without an emergency spillway: a conduit with a cross-sectional area of 3 square feet or more, an inlet that will not clog, and an elbow designed to facilitate the passage of trash.

The minimum capacity of a natural or constructed emergency spillway shall be that required to pass the peak flow expected from a design storm of the frequency and duration shown in Table 1. IDNR-OWR class III permit dams shall have an emergency spillway capable of passing the peak discharge from a 100-year, 24-hour storm event less principal spillway discharge.

Emergency spillways shall provide for passing the design flow at a safe velocity to a point downstream where the dam will not be endangered.

Constructed emergency spillways are open channels that usually consist of an inlet channel, a control section, and an exit channel. They shall be stable for the material in which the spillway is to be constructed. The emergency spillway shall have a bottom width of not less than 10 feet.

Upstream from the control section, the inlet channel shall be level for the distance needed to protect and maintain the crest elevation of the spillway. The inlet channel may be curved to fit existing topography. The grade of the exit channel of a constructed emergency spillway shall fall within the range established by discharge requirements and permissible velocities. Design procedures and details for vegetated earth emergency spillways may be found in the NRCS Engineering Field Handbook, the NRCS National Engineering Handbook, and NRCS Technical Release 52, or other references specified by the local regulatory authorities.

Foundation cutoff - A cutoff of relatively impervious material shall be provided under the dam if necessary. The cutoff

shall be located at or upstream from the centerline of the dam. It shall extend up the abutments as required and be deep enough to extend into a relatively impervious layer or provide for a stable dam when combined with seepage control. The cutoff trench shall have a bottom width adequate to accommodate the equipment used for excavation, backfill, and compaction operations. Side slopes shall not be steeper than one horizontal to one vertical.

Seepage control - Seepage control is to be included if:

1. Pervious layers are not intercepted by the cutoff,
2. Seepage creates swamping downstream,
3. Such control is needed to insure a stable embankment,
4. Special problems require drainage for a stable dam.

Seepage may be controlled by:

1. Foundation, abutment, or embankment drains,
2. Reservoir blanketing,
3. A combination of these measures.

Earth embankment - The minimum top width for a dam is shown in Table 4. If the embankment top is to be used as a public road, the minimum width shall be 16 feet for one-way traffic and 26 feet for two-way traffic. Guardrails or other safety measures shall be used where necessary and shall meet the requirements of the responsible road authority.

The combined upstream and downstream side slopes of the settled embankments shall not be less than five horizontal to one vertical, and neither

slope shall be steeper than two horizontal to one vertical. All slopes must be designed to be stable, even if flatter side slopes are required.

If needed to protect the slopes of the dam, special measures, such as berms, rock riprap, sand-gravel, soil cement, or special vegetation, shall be provided.

The minimum elevation of the top of the settled embankment shall be 1 foot above the water surface in the reservoir with the emergency spillway flowing at design depth. The minimum difference in elevation between the crest of the emergency spillway and the settled top of the dam shall be 2 feet for all dams having more than 20 acres drainage area or more than 20 feet in effective height.

The design height of the dam shall be increased by the amount needed to insure that after settlement the height of the dam equals or exceeds the design height. This increase shall not be less than 5 percent, except where detailed soil testing and laboratory analysis show that a lesser amount is adequate.

Excavated impoundments:

Runoff - Provisions shall be made for a pipe and emergency spillway if necessary. Runoff flow patterns shall be considered when locating the pit and placing the spoil.

Side slopes - Side slopes of excavated ponds shall be stable and shall not be steeper than one horizontal to one vertical.

Perimeter form - If the structures are to be used for recreation or are highly

visible to the public, the perimeter or edge should be curvilinear.

Inlet protection - If surface water enters the pond in a natural or excavated channel, the side slope of the impoundment shall be protected against erosion.

Excavated material - The material excavated from the pond shall be placed so that its weight will not endanger the stability of the pond side slopes and so that it will not be washed back into the pond by rainfall. It shall be disposed of in one of the following ways:

1. Uniformly spread to a height that does not exceed 3 feet, with the top graded to a continuous slope away from the impoundment.
2. Uniformly placed or shaped reasonably well, with side slopes assuming a natural angle of repose. The excavated material will be placed at a distance equal to the depth of the impoundment but not less than 12 feet from the edge of the impoundment.
3. Shaped to a designed form that blends visually with the landscape
4. Used for low embankment and leveling.
5. Hauled away.

Vegetation - Disturbed areas that are not to be cultivated shall be established as soon as practicable after construction. Seedbed preparation, seeding, fertilizing and mulching shall comply with practice standards [PERMANENT VEGETATION 880](#) or [TEMPORARY SEEDING 965](#).

CONSIDERATIONS

Site safety - Impoundments are potential attractive nuisances and safety aspects must be considered in their design and layout. If the area is used or may be used for recreation, it is recommended that warning signs be erected, that lifesaving equipment be available on site and that emergency instructions be posted in a conspicuous location.

Visual resource design - The visual design of impoundments shall be carefully considered in areas of high public visibility and those associated with recreation. The underlying criterion for all visual design is appropriateness. The shape and form of ponds, excavated material, and plantings are to relate visually to their surroundings and to their function.

The embankment may be shaped to blend with the natural topography. The edge of the impoundment may be shaped so that it is generally curvilinear rather than rectangular. Excavated material can be shaped so that the final form is smooth, flowing, and fitting to the adjacent landscape rather than angular geometric mounds. If feasible, islands may be added for visual interest and to attract wildlife.

Impoundments for water supply should have adequate drainage area to fill at least yearly. As a minimum, drainage area, in acres, where water supply is a primary purpose, shall equal permanent storage in acre-feet.

PLANS AND SPECIFICATIONS

Plans and specifications for installing full flow impoundment structures shall be in keeping with this standard and shall

describe the requirements for installing the practice to achieve its intended purpose. Items that specifications should address, if applicable, and appropriate construction/material specifications, standard drawings and other standards are as follows:

Site and foundation preparation - All site and foundation areas shall be prepared and maintained in such a manner that earthfill placement or other specified treatments allow the practice to achieve its intended purpose. Applicable construction specifications may include: [1 CLEARING](#), [2 CLEARING AND GRUBBING](#), [8 MOBILIZATION](#), [10 WATER FOR CONSTRUCTION](#), and [11 REMOVAL OF WATER](#).

Applicable material specifications may include: [521 AGGREGATES FOR DRAINFILL FILTERS](#), and [592 GEOTEXTILES](#).

Applicable standard drawings may include drawing number [IL-515 DIVERSION PLAN](#), [IL-585 EARTH DAM STRUCTURE PLAN](#), [IL-630 STABILIZED CONSTRUCTION ENTRANCE](#), [IL-650 SUMP PIT PLAN](#), and [IL-670 TEMPORARY SLOPE DRAIN PLAN](#).

Other applicable standards may include: [DIVERSION 815](#), [SUMP PIT 950](#), [TEMPORARY SLOPE DRAIN 970](#), and [TEMPORARY STREAM CROSSING 975](#).

Excavations and earthfill - All specified excavation shall be preformed and earthfills shall be placed in such a manner that allows the practice to achieve its intended purpose. Applicable construction specifications may include: [10 WATER FOR](#)

[CONSTRUCTION](#), [21 EXCAVATION](#), [23 EARTHFILL](#), [24 DRAINFILL](#), [25 ROCKFILL](#), [26 SALVAGING AND SPREADING TOPSOIL](#), [61 LOOSE ROCK RIPRAP](#), [62 GROUTED ROCK RIPRAP](#), and [95 GEOTEXTILE](#).

Applicable material specifications may include: [521 AGGREGATES FOR DRAINFILL AND FILTERS](#), [523 ROCK FOR RIPRAP](#), and [592 GEOTEXTILE](#).

Applicable standard drawings may include: [IL-585 EARTH DAM STRUCTURE PLAN](#).

Spillway structures - All spillways including inlet and outlet structures shall be constructed or installed in a manner that allows the practice to achieve its intended purpose. Materials and construction techniques specified shall be appropriate for the intended life and hazard classification of the practice. Where available, manufacturer's installation recommendations may be included in specifications. Applicable construction specifications may include: [24 DRAINFILL](#), [25 ROCKFILL](#), [32 STRUCTURE CONCRETE](#), [34 STEEL REINFORCEMENT](#), [41 REINFORCED CONCRETE PRESSURE PIPE PRINCIPAL SPILLWAY CONDUITS](#), [42 CONCRETE PIPE CONDUITS AND DRAINS](#), [43 CLAY PIPE](#), [51 CORRUGATED METAL PIPE](#), [52 STEEL PIPE](#), [53 DUCTILE-IRON PIPE](#), [61 LOOSE ROCK RIPRAP](#), [62 GROUTED ROCK RIPRAP](#), [64 WIRE MESH GABIONS](#), [71 WATER CONTROL GATES](#), [81 METAL FABRICATION AND INSTALLATION](#), [83 TIMBER FABRICATION & INSTALLATION](#), and [95 GEOTEXTILES](#).

Applicable material specifications may include: 521 AGGREGATES FOR DRAINFILL and FILTERS, 522 AGGREGATES FOR CONCRETE, 523 ROCK FOR RIPRAP, 531 PORTLAND CEMENT, 532 AIR ENTRAINING ADMIXTURES, 534 CURING COMPOUND, 535 PREFORMED EXPANSION JOINT FILLER, 536 SEALING COMPOUND, 537 NON-METALLIC WATERSTOPS, 538 METAL WATERSTOPS, 539 STEEL REINFORCEMENT, 541 REINFORCED CONCRETE PRESSURE PIPE, 542 CONCRETE CULVERT PIPE, 544 CLAY PIPE AND DRAIN TILE, 547 PLASTIC (PVC, PE, ABS) PIPE, 551 METALLIC COATED CORRUGATED STEEL PIPE, 552 ALUMINUM CORRUGATED PIPE, 554 STEEL PIPE & FITTINGS, 581 METAL, 582 GALVANIZING, 584 STRUCTURAL TIMBER AND LUMBER, 585 WOOD PRESERVATIVES AND TREATMENT, and 592 GEOTEXTILE.

Applicable standard drawings may include: IL-543 INLET FOR UNDERGROUND OUTLET, IL-545 CULVERT FLARED END METAL SECTION, IL-576 HEADWALL & SAFETY GUARD FOR PIPE RISERS, IL-577 HOOD INLET WITH BAFFLE FOR CMP, IL-578 CMP DROP INLET & BAFFLE, IL-579 CMP PIPE DIAPHRAGM, IL-580 COUPLING BAND FOR CMP, IL-581 TIMBER PROP FOR 18" - 30" DIAMETER CMP, IL-582 TIMBER PROP FOR 36" - 48" DIAMETER CMP, IL-583 DROP INLET STRUCTURE PLAN, IL-584 HOOD INLET STRUCTURE PLAN, IL-585 EARTH DAM STRUCTURE PLAN, IL-586 CMP SUPPORT, IL-590 TRASH RACKS FOR PIPE DROP INLET, IL-591 TRASH RACKS FOR HOODED INLET, IL-592 DETAIL FOR PVC

CANOPY INLET, IL-593 FLEXIBLE ANTISEEP COLLAR, IL-594 CMP WATER CONTROL STRUCTURE, and IL-610 PIPE OUTLET TO FLAT AREA.

Site physical protection plan - Adequate measure shall be specified to control, on site, additional runoff and/or contaminants expected as a result of construction activities; to provide for the safety of the general public; and to provide a maintainable system of erosion protection for the constructed practice. Applicable construction specifications may include: 6 SEEDING, SPRIGGING, & MULCHING FOR PROTECTIVE COVER, 26 SALVAGING & SPREADING TOPSOIL, 27 DIVERSIONS AND WATERWAYS, 46 TILE DRAINS, 61 LOOSE ROCK RIPRAP, 62 GROUTED ROCK RIPRAP, 64 WIRE MESH GABIONS, 91 CHAIN LINK FENCE, and 95 GEOTEXTILES.

Applicable material specifications may include: 523 ROCK FOR RIPRAP and 592 GEOTEXTILES.

Applicable standard drawings may include: IL-515 DIVERSION PLAN, IL-540 WATERWAY PLAN, IL-541 ROCK CHECKS FOR WATERWAYS, IL-543 INLET FOR UNDERGROUND OUTLET, IL-595 PORTABLE SEDIMENT TANK PLAN, IL-615 SEDIMENT BASIN DEWATERING PLAN, IL-620 SILT FENCE PLAN, IL-630 STABILIZED CONSTRUCTION ENTRANCE PLAN, IL-635 STRAW BALE DIKE PLAN, and IL-660 TEMPORARY SEDIMENT TRAP.

Other applicable standards may include: DIVERSION 815, DIVERSION DIKE 820, DUST CONTROL 825, EROSION BLANKET 830, FILTER STRIP 835,

LAND GRADING 865, MULCHING 875,
PERMANENT VEGETATION 880,
PORTABLE SEDIMENT TANK 895,
ROCK OUTLET PROTECTION 910,
SILT FENCE 920, SODDING 925,
STRAW BALE BARRIER 935,
SUBSURFACE DRAIN 945,
TEMPORARY DIVERSION 955,
TEMPORARY SEDIMENT TRAP 960,
TEMPORARY SEEDING 965,
TEMPORARY SWALE 980, and
TOPSOILING 981.

If required by the IDNR-OWR, an
emergency action plan shall be filed for
permit structures.

NRCS IL August 1994

urbst841.doc

OPERATION AND MAINTENANCE

An operation and maintenance plan should be developed and concurred in by the owners/operators of the impoundment structure. The operation plan shall establish a schedule for testing all operable facilities to ensure that they function as intended, or that necessary repairs are made. The maintenance plan shall specify responsible parties for maintaining or replacing, as necessary: all vegetative components of the structure, riprap for wave protection or outlet protection, inlet and outlet works, safety features including fences and signs, and on-site erosion/water control facilities.

Procedures and responsible parties for removing and disposing of accumulated debris and/or sediment as necessary to ensure the function of the structure shall be specified. Procedures and responsible parties for repairing damage to embankment, spillway structures and other appurtenances shall be specified. The structure shall be inspected at least yearly and after every storm event causing flows through vegetated spillways or over top of embankment.

IMPOUNDMENT STRUCTURE - ROUTED

(no.)
CODE 842

(Source: Native Plant Guide for Streams and Stormwater Facilities in Northeastern Illinois)

DEFINITION

A dam or excavation which creates an impoundment to collect and store debris, sediment, or water.

PURPOSE

The purposes of this practice are to reduce sediment and/or debris in runoff waters or retard flooding, to prevent damage to downstream facilities; or to provide surface water for consumption, irrigation, wildlife habitat, recreation or fire protection.

CONDITIONS WHERE PRACTICE APPLIES

This practice applies where sediment or debris is expected to be contained in runoff waters and may impair the capacity of the watercourse or damage other structures or where a surface water supply is desirable; where storage for at least one inch of water from the contributing watershed is available and where any embankment does not exceed the limits for class III, small dams, as defined by the IDNR-OWR in

"Rules for Construction and Maintenance of Dams" and the landowner or other responsible party has secured necessary permits, if required, for design and construction from IDNR-OWR and any local governmental authorities.

CRITERIA

Investigations - sufficient investigations shall be made of the impoundment site and borrow areas to determine the suitability of site and materials for construction, water holding ability and structure stability. A complete analysis of foundation and proposed fill materials shall be made when, in the opinion of the responsible engineer, it is necessary.

Hazard/safety - structures designed under criteria found in this practice shall fall within the class III, small dam category, defined by the IDNR-OWR as follows: "*class III. Dams located where failure has low probability for causing loss of life, where there are no permanent structures for human habitation, or minimum economic loss in*

excess of that which naturally would occur downstream of the dam if the dam had not failed. A dam has a low probability for causing loss of life or minimal economic loss if it is located where its failure may cause damage to agricultural fields, timber areas, township roads, or similar type areas where people seldom are present and where there are few structures. This corresponds to US Army Corps of Engineers Low Hazard Potential and USDA NRCS class a dams."

Small dams have a total impounding capacity of less than 1000 acre-feet and dam height of less than 40 feet, where dam height is defined as "*height of dam, in feet, as measured from the natural bed of the stream or watercourse at the downstream dam slope toe of the barrier to the top of the embankment or barrier.*"

Owners of impoundment structures shall obtain all necessary permits. IDNR-OWR permits may be required for class III, small dams where:

1. The drainage area of the proposed dam is 6400 acres or more in a rural area or 640 acres or more in an urban area, or
2. The dam is 25 feet or more in height, provided that the impounding capacity is greater than 15 acre-feet, or
3. The dam has an impounding capacity of 50 acre-feet or more provided that the dam height is greater than 6 feet.

Pool capacities - structures for the impoundment of debris or sediment shall have a capacity equal to the volume of sediment or debris expected to be trapped at the site during the planned useful life of the structure. That

capacity may be proportionally reduced, if periodic removal of sediment/debris is planned.

Structures that impound water for consumptive use shall have capacity as required by local consumptive use standards.

Structures that impound water for irrigation, wildlife habitat or recreation shall have capacity and depth adequate for the intended use.

Structures that impound water for fire protection shall have a capacity of at least 4000 cubic feet per residence. That capacity shall exist between the inlet to hydrant and an elevation three feet below the permanent pool elevation.

Runoff computation - total runoff amounts and peak discharges may be computed using procedures found in NRCS Engineering Field Handbook, NRCS Engineering Handbook, SCS TR-55 and TR-20, US Army Corps of Engineers HEC-1 or other procedures designated by the appropriate regulatory authorities.

Principal spillways - non-permit, IDNR-OWR class III dams shall have a principal spillway structure capable of passing the peak discharge from the routed hydrograph from a 24-hour duration storm event of frequency specified in Table 1 with stage at or below emergency spillway crest.

IDNR-OWR class III, permit size dams shall have a principal spillway structure capable of passing the peak discharge from the routed hydrograph from a 24-hour, 25 year storm event with stage at or below the emergency spillway crest.

Acceptable procedures for flood routing include those in Chapter 11, NRCS Engineering Field Handbook, SCS TR-20, SCS TR-48, US Army Corps of Engineers HEC-1 or other procedures designated by the appropriate regulatory authorities.

For structures with flood retarding as a purpose capacity of the principal spillway shall be adequate to discharge, in 10 days or less, the floodwater storage needed to provide the desired level of protection to the downstream benefited area. Storage provided primarily for the purpose of reducing the frequency of use of the emergency spillway need not be included in this 10-day drawdown limitation. The determination of capacity must be based on consideration of the benefits that accrue to the reduction in the discharge rate, damages that may result from prolonged storage in the retarding pool, damages that may result from prolonged outflow, and limitations in water rights or other legal requirements. Longer release times may be used if warranted by downstream conditions. The discharge through gated outlets shall not be considered in determining the emptying time of the retarding pool.

The elevation of the crest of the lowest stage of the principal spillway shall be set at the elevation of the sediment pool. For dry dams, the riser shall be designed to permit design discharge at the sediment pool elevation with provisions for discharging water at lower elevations to satisfy the functional requirements of the structure.

All parts of the principal spillway, except attached gates and trash racks, shall have an expected service life equal to or greater than the design life of the

structure or provisions made for replacement.

The minimum diameter of the conduit used as a principal spillway shall be 10 inches.

The storage volume shall not be less than the expected sediment accumulation during a period equal to the design life.

The retarding storage requirements shall be contain the runoff expected to occur at a frequency consistent with the level of protection to be provided to the downstream benefited area, with proper allowance for discharge through the principal spillway. The retarding storage capacity shall be sufficient to limit the use of the emergency spillway to a permissible frequency and duration based upon consideration of the erosion resistance of the spillway material and vegetative protection to be provided.

Principal spillway structures may be conduits, weir-type straight drops, or chutes.

Principal spillway pipe conduits and fittings may be metal, as per NRCS material specifications 551 through 554 or non-metal, as per NRCS material specifications 541, 542, 544, or 547. Conduits of other materials may be used at the discretion of the appropriate regulatory authorities.

Pipe conduits should meet the following requirements:

The pipe should be capable of withstanding external loading without yielding, buckling, or cracking. Pipe strength should not be less than that of the types indicated in Table 2 for plastic

pipe and in Table 3 for corrugated aluminum and galvanized steel pipe. Flexible pipe strength shall not be less than that necessary to support the design load with maximum 5 percent deflection. The inlets and outlets should be structurally sound and made of materials compatible with that of the pipe. All pipe joints should be made watertight by the use of couplings or gaskets or by welding or caulking.

Acceptable pipe materials are cast-iron, steel, corrugated steel, or aluminum, concrete, plastic, vitrified clay with rubber gaskets, and cast-in-place reinforced concrete. Aluminum pipe will not be used in soils with pH values outside the range of 4-9. Concrete and vitrified clay pipe should be laid in a concrete bedding. Plastic pipe that will be exposed to direct sunlight should be made of ultraviolet-resistant materials and protected by coating or shielding, or provisions for replacement should be specified. Connections of plastic pipe to less flexible pipe or structures must be designed to avoid stress concentrations that could rupture the plastic. Cantilever outlet sections, if used, should be designed to withstand the cantilever load. Pipe supports should be provided when needed. Other suitable outlet protection structure devices may also be used to provide a safe outlet.

Anti-seep collars should be installed around the pipe conduit in the normal saturation zone if any of the following conditions exist:

1. The settled dam height exceeds 15 feet.
2. The conduit is of smooth exterior pipe larger than eight inches in diameter.

3. The conduit is of corrugated exterior pipe larger than 12 inches in diameter.

Anti-seep collars and their connections to the pipe should be watertight. The collar material should be compatible with pipe materials. The maximum spacing should be approximately 14 times the minimum projection of the collar measured perpendicular to the pipe. A minimum of one anti-seep collar should be used on all conduits.

Closed conduit spillways designed for pressure flow must have adequate anti-vortex devices at their inlets.

If needed to prevent clogging of the conduit, an appropriate trash guard should be installed at the inlet or riser.

For safety reasons, all vertical drop inlets should be constructed to prevent accidental injury. This may be accomplished by using a horizontal anti-vortex baffle, trash rack or guardrail.

Procedures for designing, dimensioning, and detailing pipe conduit spillways may be found in the Engineering Field handbook, the NRCS National Engineering Handbook and the Illinois Procedures and Standards for Urban Soil Erosion and Sedimentation Control or other references specified by local regulatory authorities.

Weir-type straight drops or box inlets and chutes shall be designed according to procedures in the NRCS Engineering Field Handbook, the NRCS National Engineering Handbook, and the USDA Agricultural handbook No. 301, or as specified by the local regulatory authorities.

NRCS toe wall drop structures can be used if the vertical drop is 4 feet or less, flows are intermittent, downstream grades are stable, and tailwater depth at design flow is equal to or greater than one-third of the height of the overfall.

The ratio of the capacity of drop boxes to road culverts shall be as required by the responsible road authority. The drop box capacity attached to a new or existing culvert must equal or exceed the culvert capacity at the design flow.

Emergency spillways - An emergency spillway must be provided for each dam, unless the principal spillway is large enough to pass peak discharge from the routed design hydrograph and the trash that comes to it without overtopping the dam. The following are minimum criteria for acceptable use of pipe conduit principal spillway without an emergency spillway: a conduit with a cross-sectional area of 3 feet or more, an inlet that will not clog, and an elbow designed to facilitate the passage of trash.

The minimum capacity of a natural or constructed emergency spillway shall be that required to pass the peak flow expected from the routed hydrograph from a design storm of the frequency and duration shown in Table 1. IDNR-OWR class III permit dams shall have an emergency spillway capable of passing the peak discharge from the routed hydrograph from a 100-year, 24-hour storm event less principal spillway discharge.

Emergency spillways shall provide for passing the design flow at a safe velocity to a point downstream where the dam will not be endangered.

Constructed emergency spillways are open channels that usually consist of an inlet channel, a control section, and an exit channel. They shall be stable for the material in which the spillway is to be constructed. The emergency spillway shall have a bottom width of not less than 10 feet.

Upstream from the control section, the inlet channel shall be level for the distance needed to protect and maintain the crest elevation of the spillway. The inlet channel may be curved to fit existing topography. The grade of the exit channel of a constructed emergency spillway shall fall within the range established by discharge requirements and permissible velocities. Design procedures and details for vegetated earth emergency spillways may be found in the NRCS Engineering Field Handbook, the NRCS National Engineering Handbook, and SCS Technical Release 52, or other references specified by the local regulatory authorities.

Foundation cutoff - A cutoff of relatively impervious material shall be provided under the dam if necessary. The cutoff shall be located at or upstream from the centerline of the dam. It shall extend up the abutments as required and be deep enough to extend into a relatively impervious layer or provide for a stable dam when combined with seepage control. The cutoff trench shall have a bottom width adequate to accommodate the equipment used for excavation, backfill, and compaction operations. Side slopes shall not be steeper than one horizontal to one vertical.

Seepage control - Seepage control is to be included if:

1. Pervious layers are not intercepted by the cutoff,
2. Seepage creates swamping downstream,
3. Such control is needed to insure a stable embankment,
4. Special problems require drainage for a stable dam.

Seepage may be controlled by:

1. Foundation, abutment, or embankment drains,
2. Reservoir blanketing,
3. A combination of these measures.

Earth embankment - The minimum top width for a dam is shown in Table 4. If the embankment top is to be used as a public road, the minimum width shall be 16 feet for one-way traffic and 26 feet for two-way traffic. Guardrails or other safety measures shall be used where necessary and shall meet the requirements of the responsible road authority.

The combined upstream and downstream side slopes of the settled embankments shall not be less than five horizontal to one vertical, and neither slope shall be steeper than two horizontal to one vertical. All slopes must be designed to be stable, even if flatter side slopes are required.

If needed to protect the slopes of the dam, special measures, such as berms, rock riprap, sand-gravel, soil cement, or special vegetation, shall be provided.

The minimum elevation of the top of the settled embankment shall be 1 foot above the water surface in the reservoir with the emergency spillway flowing at design depth. The minimum difference in elevation between the crest of the

emergency spillway and the settled top of the dam shall be 2 feet for all dams having more than 20 acres drainage area or more than 20 feet in effective height.

The design height of the dam shall be increased by the amount needed to insure that after settlement the height of the dam equals or exceeds the design height. This increase shall not be less than 5 percent, except where detailed soil testing and laboratory analysis show that a lesser amount is adequate.

Excavated impoundments:

Runoff - Provisions shall be made for a pipe and emergency spillway if necessary. Runoff flow patterns shall be considered when locating the pit and placing the spoil.

Side slopes - Side slopes of excavated ponds shall be stable and shall not be steeper than one horizontal to one vertical.

Perimeter form - If the structures are to be used for recreation or are highly visible to the public, the perimeter or edge should be curvilinear.

Inlet protection - If surface water enters the pond in a natural or excavated channel, the side slope of the impoundment shall be protected against erosion.

Excavated material - The material excavated from the pond shall be placed so that its weight will not endanger the stability of the pond side slopes and so that it will not be washed back into the pond by rainfall. It shall be disposed of in one of the following ways:

1. Uniformly spread to a height that does not exceed 3 feet, with the top graded to a continuous slope away from the impoundment.
2. Uniformly placed or shaped reasonably well, with side slopes assuming a natural angle of repose. The excavated material will be placed at a distance equal to the depth of the impoundment but not less than 12 feet from the edge of the impoundment.
3. Shaped to a designed form that blends visually with the landscape
4. Used for low embankment and leveling.
5. Hauled away.

Vegetation - Disturbed areas that are not to be cultivated shall be established as soon as practicable after construction. Seedbed preparation, seeding, fertilizing and mulching shall comply with practice standards [PERMANENT VEGETATION 880](#) or [TEMPORARY SEEDING 965](#).

CONSIDERATIONS

Site safety - Impoundments are potential attractive nuisances and safety aspects must be considered in their design and layout. If the area is used or may be used for recreation, it is recommended that warning signs be erected, that lifesaving equipment be available on site and that emergency instructions be posted in a conspicuous location.

Visual resource design - The visual design of impoundments shall be carefully considered in areas of high public visibility and those associated with recreation. The underlying criterion for all visual design is appropriateness. The shape and form of ponds, excavated material, and plantings are to

relate visually to their surroundings and to their function.

The embankment may be shaped to blend with the natural topography. The edge of the impoundment may be shaped so that it is generally curvilinear rather than rectangular. Excavated material can be shaped so that the final form is smooth, flowing, and fitting to the adjacent landscape rather than angular geometric mounds. If feasible, islands may be added for visual interest and to attract wildlife.

Impoundments for water supply should have adequate drainage area to fill at least yearly. As a minimum, drainage area, in acres, where water supply is a primary purpose, shall equal permanent storage in acre-feet.

PLANS AND SPECIFICATIONS

Plans and specifications for installing full flow impoundment structures shall be in keeping with this standard and shall describe the requirements for installing the practice to achieve its intended purpose. Items that specifications should address, if applicable, and appropriate construction/material specifications, standard drawings and other standards are as follows:

Site and foundation preparation - All site and foundation areas shall be prepared and maintained in such a manner that earthfill placement or other specified treatments allow the practice to achieve its intended purpose. Applicable construction specifications may include: [1 CLEARING](#), [2 CLEARING AND GRUBBING](#), [8 MOBILIZATION](#), [10 WATER FOR CONSTRUCTION](#), and [11 REMOVAL OF WATER](#).

Applicable material specifications may include: [521 AGGREGATES FOR DRAINFILL](#) and [FILTERS](#), and [592 GEOTEXTILES](#).

Applicable standard drawings may include drawing number [IL-515 DIVERSION PLAN](#), [IL-585 EARTH DAM STRUCTURE PLAN](#), [IL-630 STABILIZED CONSTRUCTION ENTRANCE](#), [IL-650 SUMP PIT PLAN](#), and [IL-670 TEMPORARY SLOPE DRAIN PLAN](#).

Other applicable standards may include: [DIVERSION 815](#), [SUMP PIT 950](#), [TEMPORARY SLOPE DRAIN 970](#), and [TEMPORARY STREAM CROSSING 975](#).

Excavations and earthfill - All specified excavation shall be preformed and earthfills shall be placed in such a manner that allows the practice to achieve its intended purpose. Applicable construction specifications may include: [10 WATER FOR CONSTRUCTION](#), [21 EXCAVATION](#), [23 EARTHFILL](#), [24 DRAINFILL](#), [25 ROCKFILL](#), [26 SALVAGING AND SPREADING TOPSOIL](#), [61 LOOSE ROCK RIPRAP](#), [62 GROUTED ROCK RIPRAP](#), and [95 GEOTEXTILE](#).

Applicable material specifications may include: [521 AGGREGATES FOR DRAINFILL AND FILTERS](#), [523 ROCK FOR RIPRAP](#), and [592 GEOTEXTILE](#).

Applicable standard drawings may include: [IL-585 EARTH DAM STRUCTURE PLAN](#).

Spillway structures - All spillways including inlet and outlet structures shall be constructed or installed in a manner that allows the practice to achieve its

intended purpose. Materials and construction techniques specified shall be appropriate for the intended life and hazard classification of the practice. Where available, manufacturer's installation recommendations may be included in specifications. Applicable construction specifications may include: [24 DRAINFILL](#), [25 ROCKFILL](#), [32 CONCRETE FOR MINOR STRUCTURES](#), [34 STEEL REINFORCEMENT](#), [41 REINFORCED CONCRETE PRESSURE PIPE PRINCIPAL SPILLWAY CONDUITS](#), [42 CONCRETE PIPE CONDUITS AND DRAINS](#), [43 CLAY PIPE CONDUITS](#), [51 CORRUGATED METAL PIPE CONDUITS](#), [52 STEEL PIPE CONDUITS](#), [53 DUCTILE-IRON PIPE CONDUITS](#), [61 LOOSE ROCK RIPRAP](#), [62 GROUTED ROCK RIPRAP](#), [64 WIRE MESH GABIONS](#), [71 WATER CONTROL GATES](#), [81 METAL FABRICATION AND INSTALLATION](#), [83 TIMBER FABRICATION & INSTALLATION](#), and [95 GEOTEXTILES](#).

Applicable material specifications may include: [521 AGGREGATES FOR DRAINFILL](#) and [FILTERS](#), [522 AGGREGATES FOR CONCRETE](#), [523 ROCK FOR RIPRAP](#), [531 PORTLAND CEMENT](#), [532 AIR ENTRAINING ADMIXTURES](#), [534 CURING COMPOUND](#), [535 PREFORMED EXPANSION JOINT FILLER](#), [536 SEALING COMPOUND](#), [537 NON-METALLIC WATERSTOPS](#), [538 METAL WATERSTOPS](#), [539 STEEL REINFORCEMENT](#), [541 REINFORCED CONCRETE PRESSURE PIPE](#), [542 CONCRETE CULVERT PIPE](#), [544 CLAY PIPE AND CLAY DRAIN TILE](#), [547 PLASTIC \(PVC, PE, ABS\) PIPE](#), [551 METALLIC COATED CORRUGATED STEEL PIPE](#), [552](#)

ALUMINUM CORRUGATED PIPE, 554 STEEL PIPE & FITTINGS, 581 METAL, 582 GALVANIZING, 584 STRUCTURAL TIMBER AND LUMBER, 585 WOOD PRESERVATIVES AND TREATMENT, and 592 GEOTEXTILE.

Applicable standard drawings may include: IL-543 INLET FOR UNDERGROUND OUTLET METAL, IL-545 CULVERT FLARED END SECTION, IL-576 HEADWALL SAFETY GUARD FOR PIPE RISERS, IL-577 HOOD INLET WITH BAFFLE FOR CMP, IL-578 CMP DROP INLET & BAFFLE, IL-579 CMP PIPE DIAPHRAGM, IL-580 COUPLING BAND FOR CMP, IL-581 TIMBER PROP FOR 18" - 30" DIAMETER CMP, IL-582 TIMBER PROP FOR 36" - 48" DIAMETER CMP, IL-583 DROP INLET STRUCTURE PLAN, IL-584 HOOD INLET STRUCTURE PLAN, IL-585 EARTH DAM STRUCTURE PLAN, IL-586 CMP SUPPORT, IL-590 TRASH RACKS FOR PIPE DROP INLET, IL-591 TRASH RACKS FOR HOODED INLET, IL-592 DETAIL FOR PVC CANOPY INLET, IL-593 FLEXIBLE ANTISEEP COLLAR, and IL-610 PIPE OUTLET TO FLAT AREA.

Site physical protection plan - Adequate measure shall be specified to control, on site, additional runoff and/or contaminants expected as a result of construction activities; to provide for the safety of the general public; and to provide a maintainable system of erosion protection for the constructed practice. Applicable construction specifications may include: 6 SEEDING, SPRIGGING, & MULCHING FOR PROTECTIVE COVER, 26 SALVAGING & SPREADING TOPSOIL, 27 DIVERSIONS AND WATERWAYS, 46 TILE DRAINS, 61 LOOSE ROCK

RIPRAP, 62 GROUTED ROCK RIPRAP, 64 WIRE MESH GABIONS, 91 CHAIN LINK FENCE, and 95 GEOTEXTILES.

Applicable material specifications may include: 523 ROCK FOR RIPRAP and 592 GEOTEXTILES.

Applicable standard drawings may include: IL-515 DIVERSION PLAN, IL-540 WATERWAY PLAN, IL-541 ROCK CHECKS FOR WATERWAYS, IL-543 INLET FOR UNDERGROUND OUTLET, IL-595 PORTABLE SEDIMENT TANK PLAN, IL-615 SEDIMENT BASIN DEWATERING PLAN, IL-620 SILT FENCE PLAN, IL-630 STABILIZED CONSTRUCTION ENTRANCE PLAN, IL-635 STRAW BALE BARRIER PLAN, and IL-660 TEMPORARY SEDIMENT TRAP.

Other applicable standards may include: DIVERSION 815, DIVERSION DIKE 820, DUST CONTROL 825, EROSION BLANKET 830, FILTER STRIP 835, LAND GRADING 865, MULCHING 875, PERMANENT VEGETATION 880, PORTABLE SEDIMENT TANK 895, ROCK OUTLET PROTECTION 910, SILT FENCE 920, SODDING 925, STRAW BALE BARRIER 935, SUBSURFACE DRAIN 945, TEMPORARY DIVERSION 955, TEMPORARY SEDIMENT TRAP 960, TEMPORARY SEEDING 965, TEMPORARY SWALE 980, and TOPSOILING 981.

OPERATION AND MAINTENANCE

An operation and maintenance plan should be developed and concurred in by the owners/operators of the impoundment structure. The operation plan shall establish a schedule for

testing all operable facilities to ensure that they function as intended, or that necessary repairs are made. The maintenance plan shall specify responsible parties for maintaining or replacing, as necessary: all vegetative components of the structure, riprap for wave protection or outlet protection, inlet and outlet works, safety features including fences and signs, and on-site erosion/water control facilities.

Procedures and responsible parties for removing and disposing of accumulated debris and/or sediment as necessary to ensure the function of the structure shall be specified. Procedures and responsible parties for repairing damage to embankment, spillway structures and other appurtenances shall be specified. The structure shall be inspected at least yearly and after every storm event causing flows through vegetated spillways or over top of embankment.

If required by the IDNR-OWR, an emergency action plan shall be filed for permit structures.

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

INFILTRATION TRENCH

(ft.)
CODE 847

(Source: Center for Watershed Protection)

DEFINITION

An excavated trench filled with coarse granular material in which stormwater runoff is collected for temporary storage and infiltration.

PURPOSE

The purposes of this practice are to reduce runoff volume and peak discharges from a site, increase groundwater recharge and baseflow, and to filter soluble contaminants out of runoff before it reaches receiving waters. Infiltration trenches are not intended to remove coarse sediments.

CONDITIONS WHERE PRACTICE APPLIES

This permanent site development practice applies to small drainage areas not exceeding 5 acres.

The soils surrounding the trench shall have permeability rates of 0.5 to 2.41 in/hr, a minimum available water capacity of 0.15 in/in, and clay content

less than 35%. These values can be found in published soil surveys.

Because infiltration trenches are not designed to filter coarse particulate matter, appropriate sediment control devices must be included in the site design and must be installed prior to the construction of the trench.

CRITERIA

Design capacity shall be a minimum volume of 0.5 inches of runoff per acre of drainage area.

The capacity of the trench shall be based on the porosity (% voids) of the coarse aggregate used in the system. If test data is not available, use 40% porosity for the coarse aggregate.

The trench shall be filled with coarse aggregate which meets IDOT CA-1, or CA-3 gradation. The bottom 6 inch layer in the trench shall be sand which meets IDOT CA-14, CA-15 or CA-16 gradation. The coarse aggregate shall be separated from the soil surrounding the trench by a filter fabric. The fabric

shall meet the requirements in material specification [592 GEOTEXTILE](#) Table 1 or 2, Class 1 with an apparent opening size of at least 30 for non-woven and 50 for woven. The fabric shall extend through the coarse aggregate one foot below the trench surface to prevent plugging. The filter fabric may be extended across the trench bottom in place of the sand layer.

Infiltration trenches shall be designed to dewater within 72 hours. Table 1 lists the maximum trench depths allowed for various soil types for 48 and 72 hour dewatering time periods. The permeability rate shall be field verified to a depth 3 feet below the trench bottom.

The width of the infiltration trench is determined using the design volume and final trench depth values.

All infiltration trenches must have an overflow component since they are not designed to handle large runoff volumes.

The location of the infiltration trench shall meet the following requirements. The bottom of the trench shall be a minimum of 3 feet above the seasonal high water table, bedrock, an impermeable soil layer or dissimilar soil layer. The trench shall be a minimum of 20 feet downslope or 100 feet upslope from any building foundation. The trench shall be a minimum of 100 feet from drinking water wells, septic tanks, drainfields etc. The trench shall not be installed on landslopes greater than 15% and shall be at least 50 feet from where landslopes are greater than 15%. The trench shall not be installed in fill soils.

Observation wells shall be included with the infiltration trench to enable inspection of their performance.

Observation wells shall be constructed of 6-8 inch diameter perforated pipe embedded vertically through the aggregate and extended above the ground surface. The surface protrusion shall be capped and protected against vandalism. A well anchor shall be secured to the pipe to prevent the well from being pulled out of the trench. The well anchor may consist of a metal plate or bar secured at or near the bottom of the observation well.

CONSIDERATIONS

It is absolutely critical that settleable particles and floatable organic materials be removed from runoff water before it enters the infiltration trench. The trench will clog and become nonfunctional if excessive particulate matter is allowed to enter the trench. Runoff filtering practices such as practice standard [FILTER STRIP 835](#), and [GRASSED LINED CHANNEL 840](#) must be installed upstream of the trench. If there are uncontrolled sources of grease or oil, grease traps also need to be installed upstream of the trench.

For the same reasons, control of construction site sediment is critical during trench installation. Appropriate sediment control practices such as practice standards [TEMPORARY SEDIMENT TRAP 960](#) and [SILT FENCE 920](#) must be installed and maintained during construction. A more reliable alternative is to wait to install the trench until construction is complete and the upstream drainage area is stabilized.

Infiltration trenches should not be installed if there is not a reliable long term commitment to upstream sediment control.

Care must be taken to prevent groundwater contamination by not installing infiltration trenches in highly permeable sand or gravel seams that are directly connected to underlying aquifers.

For removal of soluble contaminants, a 12 inch soil layer with a cation exchange capacity (CEC) of 0.5 millieq/100g or greater needs to be present. In Illinois, most soils that meet the permeability, available water capacity and clay content criteria will have a CEC of 0.5 millieq/100g or greater.

PLANS AND SPECIFICATIONS

Plans and specifications for installing infiltration trenches shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

1. System location
2. Depth, width and length
3. Aggregate gradation
4. Filter fabric requirements
5. Observation well details
6. Identification of upstream sediment control BMPs

All plans shall include installation, inspection, and maintenance schedules with the responsible party identified.

Standard drawing [INFILTRATION TRENCH IL-547](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

During the first year after construction, the observation well should be inspected after each significant rainfall event to ensure that the trench is draining properly. Thereafter, the well should be inspected seasonally.

If the trench clogs, it may be necessary to remove and replace all or part of the filter fabric and possibly the coarse aggregate. The frequency of such repairs will depend on the adequacy of pre-treatment as discussed previously.

Most of the maintenance should be concentrated on the pretreatment practices, such as filter strips and swales, upstream of the trench to ensure that sediment does not reach the infiltration trench.

Maintenance needs are to be discussed with the landowner or operator who is responsible for maintaining the practice.

Values based on a Soil Porosity of 40 %.

Maximum allowable depth computed by:

$$d = \frac{(fc)(T)100}{P}$$

where

d = depth	inch
fc = permeability rate	inch/hour
T = time to dewater	hour
P = porosity (% voids)	%

Design Volume of Trench = Required Runoff Volume / Porosity

Porosity = Volume of Voids / Total Volume

Required Runoff Volume = Volume of Voids in Trench

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

INLET PROTECTION - BLOCK & GRAVEL

(no.)
CODE 850

(Source: NC Erosion and Sediment Control Planning and Design Manual)

DEFINITION

A temporary sediment control barrier formed around a storm drain inlet by the use of standard concrete blocks and gravel.

PURPOSE

The purpose of this practice is to help prevent sediment from entering storm drains before stabilizing the contributing watershed. This practice allows early use of the storm drain system.

CONDITIONS WHERE PRACTICE APPLIES

A block and gravel type of inlet protection may be used where storm drain inlets are to be made operational before permanent stabilization of the disturbed drainage area. This method of inlet protection applies to both drop inlets and curb inlets where heavy flows are expected and an overflow capacity is necessary to prevent excessive ponding around the structure. Shallow temporary flooding after rainfall should be expected.

This practice may be used near the edge of fill material and must not divert water away from the storm drain.

This practice can be used in combination with other temporary inlet protection devices such as practice standards [INLET PROTECTION - EXCAVATED DRAIN 855](#) or [INLET PROTECTION - FABRIC DROP 860](#).

CRITERIA

The drainage area should be smaller than 1 acre unless site conditions and assurances that timely inspection and maintenance allows for frequent removal and adequate disposal of accumulated sediment.

The height of the barrier shall be at least 12 inches but no greater than 24 inches. Do not use mortar. Limit the height to prevent excess ponding and bypass flow.

Recess the first course of blocks at least 2 inches below the crest opening of the storm drain for lateral support. Support subsequent courses laterally if needed.

by placing a 2 x 4-inch wood stud through the block openings that are perpendicular to the block course needing support. Lay one block on its side on each side of the bottom row for dewatering the pool.

Place hardware cloth or comparable wire mesh with 1/2 inch openings over all block openings to hold gravel in place. Place gravel just below the top of the blocks on slopes of 2:1 or flatter. The gravel shall meet the requirements for coarse aggregate with IDOT gradations of CA-1, CA-2, or CA-3.

CONSIDERATIONS

In developing areas, installation of streets and storm sewer networks usually occur before the construction of homes, businesses or other developments. During this and subsequent phases of construction, unprotected soil is susceptible to erosion. Storm sewers that are operational before their drainage areas are stabilized often carry large amounts of sediment to lakes, detention ponds, streams, or other natural or constructed drainageways. As a result, the water quality of the receiving body of water is detrimentally affected. In cases of extreme sediment loading, the storm sewer may clog completely or lose a major portion of its capacity. To avoid these problems, it is necessary to prevent sediment from entering the system at the inlets.

Storm drain inlet protection consists of several types of inlet filters and traps. Each type differs in application dependant upon site conditions and type of inlet. Not all designs are appropriate in all cases. The user must carefully select a design suitable for the needs and site conditions. Field experience has shown that inlet protection that

causes excessive ponding in an area of high construction activity may become so inconvenient that it is removed or bypassed, thus transmitting sediment-laden flows unchecked. In such situations, a structure with an adequate overflow mechanism must be utilized.

Stone is utilized as the chief ponding/filtering agent in many types of inlet protection. The various types of "coarse aggregates" which are shown are able to filter out sediment mainly through slowing down flows directed to the inlet by creating an increased flow path for the stormwater (through void space in the respective stone). The stone filtering medium by no means slows stormwater flow rate as does filter cloth and therefore cannot provide the same degree of filter efficiency when smaller silt and clay particles are introduced into stormwater flows. However, as mentioned earlier, excessive ponding in busy areas adjacent to stormwater inlets is in many cases unacceptable.

In most instances, inlet protection utilizing stone should not be the sole control measure. At the time that storm sewer inlet and associated appurtenances become operational, areas adjacent to the structures are most likely at final grade or will not be altered for extended periods. This is the time when practice standard [TEMPORARY SEEDING 965](#) and other appropriate controls should be implemented to enhance sediment-loss reductions. In addition, by varying stone sizes used in the construction of inlet protection, a greater degree of sediment removal can be obtained. As an option, filter cloth can be used with the stone in these devices to further enhance sediment removal. Notably, the potential inconvenience of excessive

ponding must be examined with these choices, especially the latter. In all designs that utilize stone with a wire-mesh support as a filtering mechanism, the stone can be completely wrapped with the wire mesh to improve stability and provide easier cleaning.

Filter fabric may be added to any of the devices that utilize coarse aggregate stone to enhance sediment removal. The fabric shall meet the requirements as shown in material specification [592 GEOTEXTILE](#) Table 1 or 2, Class 1 with an AOS of at least 30 for non-woven and 50 for woven. As a result of the significant increase in filter efficiency provided by the fabric, a larger range of stone sizes (IDOT CA-1, CA-2 or CA-3) may be utilized with such a configuration. The larger stone will help keep larger sediment masses from clogging the cloth.

Inlet protection devices are for drainage areas of one acre or less. Runoff from areas larger than one acre should be routed through a properly designed practice such as [IMPOUNDMENT STRUCTURE-ROUTED 842](#), [TEMPORARY SEDIMENT TRAP 960](#).

The best way to prevent sediment from entering the storm sewer system is to stabilize disturbed areas of the site as quickly as possible, preventing erosion and stopping sediment at its source.

PLANS AND SPECIFICATIONS

Plans and specifications for installing block and gravel inlet protection shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

1. Inlet location

2. Stone gradation
3. Wire screen hole size

All plans shall include the installation, inspection, and maintenance schedules with the responsible party identified.

Standard drawing [IL-550 INLET PROTECTION - BLOCK AND GRAVEL PLAN](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

Inspect the barrier after each runoff producing rain and make repairs as needed.

Sediment shall be removed and the trap restored to its original dimensions when the sediment has accumulated to one-half the design depth of the trap. Removed sediment shall be deposited in a suitable area in such a manner that it will not erode.

When the contributing drainage area has been adequately stabilized, remove all materials and any unstable soil, and either salvage or dispose of it properly. Bring the disturbed area to proper grade, then smooth and compact it. Appropriately stabilize all bare areas around the inlet.

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

INLET PROTECTION - EXCAVATED DRAIN

(no.)
CODE 855

(Source: NC Erosion and Sediment Control Planning and Design Manual)

DEFINITION

An excavated area in the approach to a storm drain drop inlet or curb inlet.

PURPOSE

The purpose of this practice is to help prevent sediment from entering storm drains before stabilizing the contributing watershed. This practice allows early use of the storm drain system.

CONDITIONS WHERE PRACTICE APPLIES

An excavated drain type of inlet protection may be used where storm drain drop inlets are to be made operational before permanent stabilization of the disturbed drainage area. This method of inlet protection is applicable where relatively heavy flows are expected and overflow capability and ease of maintenance are desired. Frequent maintenance is required and temporary flooding in the excavated area will occur. This practice can be used in combination with other temporary inlet protection devices such

as practices, [INLET PROTECTION-BLOCK AND GRAVEL 850](#), and [INLET PROTECTION-FABRIC DROP 860](#).

CRITERIA

Limit the drainage area to 1 acre. The minimum depth shall be 1 foot and the maximum depth shall be 2 feet as measured from the crest of the inlet structure.

Maintain side slopes around the excavated area no steeper than 2:1.

The minimum volume of excavated area around the drop inlet shall be approximately 135 yd³/acre of drainage area.

Shape the basin to fit site conditions, with the longest dimension oriented toward the longest inflow area to provide maximum trap efficiency. Where an inlet is located so as to receive concentrated flows such as in a highway median, the basin shall have a rectangular shape in a 2:1 length to

width ratio, with the length being oriented in the direction of flow.

Install provisions, such as weep holes, for draining the temporary pool to improve trapping efficiency for small storms and to avoid problems from standing water after heavy rains.

Gravel meeting the requirements for coarse aggregate with gradations of CA-1, CA-2 or CA-3, may be placed next to the storm drain inlet structure to improve filtering efficiency.

When gravel is used, the weep hole should be covered with screen wire or hardware cloth to prevent the gravel from entering the storm drain.

CONSIDERATIONS

In developing areas, installation of streets and storm sewer networks usually occurs before homes, businesses or other developments are constructed. During this and subsequent phases of construction, unprotected soil is susceptible to erosion. Storm sewers that are operational before their drainage areas are stabilized often carry large amounts of sediment to lakes, detention ponds, streams, or other natural or constructed drainageways. As a result, the water quality of the receiving body of water is detrimentally affected. In cases of extreme sediment loading, the storm sewer may clog completely or lose a major portion of its capacity. To avoid these problems, it is necessary to prevent sediment from entering the system at the inlets.

Field experience has shown that inlet protection which cause excessive ponding in areas of high construction

activity may become so inconvenient that it is removed or bypassed, thus transmitting sediment laden flows unchecked. In such situations, a structure with an adequate overflow mechanism should be utilized.

Storm drain inlet protection consists of several types of inlet filters and traps. Each type differs in application dependant upon site conditions and type of inlet. Not all designs are appropriate in all cases. The user must carefully select a design suitable for the needs and site conditions.

Stone is utilized as the chief ponding/filtering agent in many types of inlet protection. The various types of "coarse aggregates" which are depicted are able to filter out sediment mainly through slowing down flows directed to the inlet by creating an increased flow path for the stormwater (through void space in the respective stone). The stone filtering medium by no means slows stormwater flow rate as does filter cloth and therefore cannot provide the same degree of filter efficiency when smaller silt and clay particles are introduced into stormwater flows. However, as mentioned earlier, excessive ponding in busy areas adjacent to stormwater inlets is in many cases unacceptable. That is why stone must be utilized with many installations.

Fortunately, in most instances, inlet protection utilizing stone should not be the sole control measure. At the time that storm sewer inlet and associated appurtenances become operational, areas adjacent to the structures are most likely at final grade or will not be altered for extended periods. This is the time when practice standard

[TEMPORARY SEEDING 965](#) and other

appropriate controls should be implemented to enhance sediment-loss mitigation. In addition, by varying stone sizes used in the construction of inlet protection, a greater degree of sediment removal can be obtained. As an option, filter cloth can be used with the stone in these devices to further enhance sediment removal. Notably, the potential inconvenience of excessive ponding must be examined with these choices. In all designs that utilize stone with a wire-mesh support as a filtering mechanism, the stone can be completely wrapped with the wire mesh to improve stability and provide easier cleaning.

Filter fabric may be added to any of the devices that utilize coarse aggregate stone to enhance sediment removal. The fabric shall meet the requirements as shown in material specification [592 GEOTEXTILE](#) Table 1 or 2, Class 1 with an AOS of at least 30 for non-woven and 50 for woven. As a result of the significant increase in filter efficiency provided by the fabric, a larger range of stone sizes (IDOT CA-1, CA-2 or CA-3) may be utilized with such a configuration. The larger stone will help keep larger sediment masses from clogging the cloth. Notably, significant ponding may occur at the inlet if filter cloth is utilized in this manner.

Inlet protection devices are for drainage areas of one acre or less. Runoff from areas larger than one acre should be routed through a properly designed practice such as [IMPOUNDMENT STRUCTURE-ROUTED 842](#) or [TEMPORARY SEDIMENT TRAP 960](#).

A temporary berm may need to be constructed downstream of the inlet

protection device to prevent bypass flows.

The best way to prevent sediment from entering the storm sewer system is to stabilize the disturbed area of the site as quickly as possible, preventing erosion and stopping sediment at its source.

PLANS AND SPECIFICATIONS

Plans and specifications for installing excavated drain inlet protection shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

1. Inlet location.
2. Basin length, width and depth.
3. Detail around inlet structure.

All plans shall include the installation, inspection, and maintenance schedules with the responsible party identified.

Standard drawing [IL-555 INLET PROTECTION -EXCAVATED DRAIN PLAN](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

Inspect, clean, and properly maintain the excavated basin after every storm until the contributing area has been permanently stabilized. To provide satisfactory basin efficiency, remove sediment when the volume of the basin has been reduced by one-half. Spread all excavated material evenly over the surrounding land area or stockpile and stabilize it appropriately.

After the contributing drainage area has been stabilized, remove the gravel and accumulated sediment, plug the weep

holes, backfill to final grade and
establish vegetation.

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

INLET PROTECTION - FABRIC DROP

(no.)
CODE 860

(Source: USDA - Natural Resources Conservation Service - Illinois)

DEFINITION

A temporary fabric barrier placed around a drop inlet.

PURPOSE

The purpose of this practice is to help prevent sediment from entering storm drains during construction operations. This practice allows early use of the storm drainage system.

CONDITIONS WHERE PRACTICE APPLIES

A fabric drop type of inlet protection may be used where storm drain inlets are to be made operational before permanent stabilization of the disturbed drainage area. This method of inlet protection is effective where the inlet drains a small, nearly level area with slopes generally less than 5% and where shallow sheet flows not exceeding 1 cfs are expected. The immediate land area around the inlet should be relatively flat (less than 1% slope) and located so that accumulated sediment can be easily removed. This method should not be

used in areas receiving concentrated flows, such as in street or highway medians.

CRITERIA

The maximum drainage area shall not exceed 1 acre per inlet.

The maximum height of fabric above the crest of the drop inlet shall be 1.5 feet. This height allows a shallow temporary de-silting pool to form behind the fabric but limits the pressure against the fabric if overtopping occurs. The selected height of the top of the barrier should allow overflow to the drop inlet and not let overflow bypass the inlet to unprotected lower areas. It may be necessary to build a temporary dike on the downslope side of the structure to prevent bypass flows.

For fabric barriers, use stakes of 2 x 4-inch wood (preferred) or equivalent metal with a minimum length of 3 feet. Space the stakes a maximum of 3 feet apart, and securely drive them into the

ground to a depth of approximately 18 inches.

Drive the stakes close to the drop inlet so that overflow will fall directly into the structure and not on unprotected soil.

To provide needed stability to the installation, make a frame around the stakes a maximum of 1.5 ft above the top of the drop inlet. This will serve as a stable crest for overflow during rainfall. Place the bottom 12 inches of the fabric in a trench and backfill the trench with 12 inches of compacted soil or six inches of crushed gravel.

Fasten fabric securely by staples or wire to the stakes and frames. Joints must be overlapped to the next stake.

Improved performance and sediment storage volume can be obtained by excavating the area. See practice standard, [INLET PROTECTION - EXCAVATED DRAIN 855](#). The fabric shall meet the requirements as shown in Material Specification [592 GEOTEXTILE](#) Table 1 or 2, Class 1 with an AOS of at least 30 for non-woven and 50 for woven.

CONSIDERATIONS

In developing areas, installation of streets and storm sewer networks usually occur before the construction of homes, businesses or other developments. During this and subsequent phases of construction, unprotected soil is susceptible to erosion. Storm sewers that are operational before their drainage areas are stabilized often carry large amounts of sediment to lakes, detention ponds, streams, or other natural or constructed drainageways. As a result, the water

quality of the receiving body of water is detrimentally affected. In cases of extreme sediment loading, the storm sewer may clog completely or lose a major portion of its capacity. To avoid these problems, it is necessary to prevent sediment from entering the system at the inlets.

Storm drain inlet protection consists of several types of inlet filters and traps. Each type differs in application dependant upon site conditions and type of inlet. Not all designs are appropriate in all cases. The user must carefully select a design suitable for the needs and site conditions.

Inlet protection devices are for drainage areas of one acre or less. Runoff from areas larger than one acre should be routed through a properly designed practice such as [IMPOUNDMENT STRUCTURE-ROUTED 842](#) or [TEMPORARY SEDIMENT TRAP 960](#).

In some instances, a wire mesh may be needed to reinforce the fabric and supporting posts. This should be used in areas where concentrated flows may occur or where timely maintenance may be a concern. If used, the wire mesh shall have a maximum opening of 6 inches.

A temporary berm may need to be constructed downstream of the inlet protection device to prevent bypass.

The best way to prevent sediment from entering the storm sewer system is to stabilize the disturbed area of the site as quickly as possible, preventing erosion and stopping sediment at its source.

PLANS AND SPECIFICATIONS

NRCS IL February 1994

urbst860.doc

The plans and specifications for installing fabric drop inlet protection shall be in keeping with this standard and shall describe requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

1. Inlet location.
2. Type and size support posts.
3. Fabric material requirements.
4. Detail around inlet structure.

All plans shall include the installation, inspection, and maintenance schedules with the responsible party identified.

Standard drawing [IL-560 INLET PROTECTION - FABRIC DROP PLAN](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

Inspect the fabric barrier after each rain and make repairs as needed.

Sediment deposits should be removed after each rainfall to provide adequate storage volume for the next rain. The sediment must be removed when the level of deposition reaches approximately one-half the height of the barrier. Be careful not to damage or undercut the fabric during sediment removal.

When the contributing drainage area has been adequately stabilized, remove all materials and any unstable sediment and dispose of them properly. Bring the disturbed area to the grade of the drop inlet and smooth and compact it. Appropriately stabilize all bare areas around the inlet.

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

INLET PROTECTION - GRAVEL & WIRE MESH

(no.)
CODE 861

(Source: MN Protecting Water Quality in Urban Areas)

DEFINITION

A temporary sediment control barrier formed around a storm drain inlet by the use of gravel and wire mesh.

PURPOSE

The purpose of this practice is to help prevent sediment from entering storm drains until the contributing watershed is stabilized.

CONDITIONS WHERE PRACTICE APPLIES

A gravel and wire mesh type of inlet protection applies where new or existing storm sewers receive sediment-laden runoff.

This method of inlet protection applies to both drop inlets and curb inlets where heavy flows are expected and ponding in front of the structure is not likely to cause inconvenience or damage to adjacent structures and unprotected areas.

This practice can be used in combination with other temporary inlet protection devices such as practice standards [INLET PROTECTION – BLOCK & GRAVEL 850](#), [INLET PROTECTION - EXCAVATED DRAIN 855](#), [INLET PROTECTION - FABRIC DROP 860](#) or [INLET PROTECTION – STRAW BALE BARRIER 863](#).

CRITERIA

The drainage area to each gravel and wire inlet protection shall be one acre or less.

Hardware cloth or comparable wire mesh with 1/2 inch openings shall be placed over the inlet structure extending a minimum of 12 inches beyond each side of the inlet opening. If more than one strip of mesh is necessary, the strips shall be overlapped a minimum of 6 inches.

Gravel shall be placed over the wire mesh to a minimum depth of 12 inches. The gravel shall extend beyond the inlet opening a minimum of 18 inches on all

sides. The gravel shall meet the requirements for coarse aggregate with IDOT gradation of CA-1 or CA-3.

Filter fabric may be added under the coarse aggregate to enhance sediment removal. The fabric shall meet the requirements as shown in material specification [592 GEOTEXTILE](#) Table 1 or 2, Class 1 with an AOS of at least 30 for non-woven and 50 for woven. As a result of the significant increase in filter efficiency provided by the fabric, a larger range of stone sizes (IDOT CA-1, CA-2 or CA-3) may be utilized with such a configuration. The choice to use filter fabric must also consider the larger ponding area that will result.

CONSIDERATIONS

In developing areas, installation of streets and storm sewer networks usually occur before the construction of homes, businesses or other developments. During this, and subsequent phases of construction, unprotected soil is susceptible to erosion. Storm sewers that are operational before their drainage areas are stabilized often carry large amounts of sediment to lakes, detention ponds, streams, or other natural or constructed drainageways. As a result, the water quality of the receiving body of water is detrimentally affected. In cases of extreme sediment loading, the storm sewer may clog completely or lose a major portion of its capacity. To avoid these problems, it is necessary to prevent sediment from entering the system at the inlets.

Storm drain inlet protection consists of several types of inlet filters and traps. Each type differs in application dependant upon site conditions and type

of inlet. Not all designs are appropriate in all cases. The user must carefully select a design suitable for the needs and site conditions. Field experience has shown that inlet protection that causes excessive ponding in an area of high construction activity may become so inconvenient that it is removed or bypassed, thus transmitting sediment-laden flows unchecked. In such situations, a structure with an adequate overflow mechanism must be utilized.

Stone is utilized as the chief ponding/filtering agent in many types of inlet protection. The various types of "coarse aggregates" are able to filter out sediment mainly through slowing down flows directed to the inlet by creating an increased flow path for the stormwater (through void space in the respective stone). The stone filtering medium does not slow stormwater flow rate as well as filter cloth and therefore cannot provide the same degree of filter efficiency when smaller silt and clay particles are introduced into stormwater flows. In all designs that utilize stone with a wire-mesh support as a filtering mechanism, the stone can be completely wrapped with the wire mesh to improve stability and provide easier cleaning.

In most instances, inlet protection utilizing stone should not be the sole control measure. At the time that storm sewer inlet and associated appurtenances become operational, areas adjacent to the structures are most likely at final grade or will not be altered for extended periods. This is the time when practice standard [TEMPORARY SEEDING 965](#) and other appropriate controls should be implemented to reduce soil erosion.

The best way to prevent sediment from entering the storm sewer system is to stabilize disturbed areas of the site as quickly as possible, preventing erosion and stopping sediment at its source.

Runoff from areas larger than one acre should be routed through a properly designed practice such as [IMPOUNDMENT STRUCTURE - ROUTED 842](#), or [TEMPORARY SEDIMENT TRAP 960](#).

PLANS AND SPECIFICATIONS

Plans and specifications for installing gravel and wire mesh inlet protection shall be in keeping with this standard and shall describe the requirements for applying the practice. At a minimum include the following items:

1. Inlet location
2. Stone gradation
3. Wire screen hole size
4. Filter fabric specifications if used

All plans shall include the installation, inspection, and maintenance schedules with the responsible party identified.

Standard drawing [GRAVEL & WIRE MESH INLET PROTECTION PLAN IL - 561](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

The structure shall be inspected after every runoff producing rain and repairs made as needed. When a geotextile filter fabric is used, inspection must be made more frequently as the fabric tends to "plug" quickly.

If the gravel filter becomes clogged with sediment so that it no longer adequately performs its function, the gravel must be

pulled away from the inlet, cleaned and replaced.

Sediment shall be removed and the barrier restored to its original dimensions when the sediment has accumulated to one-half the barrier height. Removed sediment shall be deposited in a suitable area in such a manner that it will not erode.

When the contributing drainage area has been adequately stabilized, remove all materials and any unstable soil, and either salvage or dispose of it properly. Bring the disturbed area to proper grade, then smooth and compact it. Appropriately stabilize all bare areas around the inlet.

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

INLET PROTECTION – SOD FILTER

(no.)
CODE 862

(Source: USDA - Natural Resources Conservation Service - Illinois)

DEFINITION

A sediment filter formed around a storm drain drop inlet by the use of sod.

PURPOSE

The purpose of this practice is to help prevent sediment and mulch materials from entering storm drains before permanent seeding has become established in the contributing watershed.

CONDITIONS WHERE PRACTICE APPLIES

This method of inlet protection is applicable only for drop inlets at the time when permanent seeding of the contributing drainage area is completed.

CRITERIA

The drainage area shall be limited to 1 acre.

Sod shall be placed to form a turf mat that covers the soil for a minimum of 4 feet from each side of the inlet structure.

Final grading, soil preparation and installation of sod shall follow criteria in practice standard [SODDING 925](#).

For sites where permanent seeding has not been completed, practice standards [INLET PROTECTION - BLOCK & GRAVEL 850](#), [INLET PROTECTION – EXCAVATED DRAIN 855](#), [INLET PROTECTION – FABRIC DROP 860](#), [INLET PROTECTION – GRAVEL & WIRE MESH 861](#), or [INLET PROTECTION – STRAW BALE BARRIER 863](#) shall be utilized, as appropriate.

Filter fabric may be used under the storm sewer grate to enhance sediment removal. The fabric shall meet the requirements as shown in material specification [592 GEOTEXTILE](#), Table 1 or 2 Class 1 with an AOS of at least 30 for non-woven and 50 for woven. Use of the fabric may increase the frequency of maintenance.

CONSIDERATIONS

Storm drain inlet protection consists of several types of inlet filters and traps.

Each type differs in application dependant upon site conditions and type of inlet. Not all designs are appropriate in all cases. The user must carefully select a design suitable for the needs and site conditions.

The best way to prevent sediment from entering the storm sewer system is to stabilize disturbed areas of the site as quickly as possible, preventing erosion and stopping sediment at its source.

For this practice to have its maximum effect, the sod must be flush with the surrounding ground surface.

Runoff from areas larger than one acre should be routed through a properly designed practice such as [IMPOUNDMENT STRUCTURE - ROUTED 842](#), or [TEMPORARY SEDIMENT TRAP 960](#).

PLANS AND SPECIFICATIONS

Plans and specifications for installing sod filter inlet protection shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

1. Inlet location
2. Filter fabric specifications if used
3. Site preparation
4. Fertilization
5. Installation techniques
6. Sod type, quality and quantity
7. Watering

All plans shall include the installation, inspection, and maintenance schedules with the responsible party identified.

Standard drawing [SOD FILTER INLET PROTECTION PLAN IL-562](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

The structure shall be inspected after every runoff producing rain and repairs made as needed.

If the grate or filter fabric becomes clogged with sediment or mulch materials so that it no longer adequately performs its function, they must be pulled away from the inlet, and the grate and filter fabric cleaned and replaced.

Removed materials shall be deposited in a suitable area in such a manner that it will not cause problems.

urbst862.doc

INLET PROTECTION – STRAW BALE BARRIER

(no.)
CODE 863

(Source: Lake County Soil and Water Conservation District)

DEFINITION

A temporary sediment control barrier formed around a storm drain drop inlet consisting of a row of entrenched and anchored straw bales.

PURPOSE

The purpose of this practice is to help prevent sediment from entering storm drains until the contributing watershed is stabilized.

CONDITIONS WHERE PRACTICE APPLIES

A straw bale barrier type of inlet protection applies where new or existing storm sewers receive sediment-laden runoff. This method is applicable for drop inlets only.

This method is applicable where the inlet drains a small, nearly level area with slopes generally less than 5% and shallow sheet flows not exceeding 0.5 cfs are expected.

The immediate land area around the inlet should be relatively flat (less than 1% slope) and located so that accumulated sediment can be easily removed.

This method does not apply to inlets receiving concentrated flows, such as in street or highway medians.

This method applies where effectiveness is required for 3 months or less.

This practice can be used in combination with other temporary inlet protection devices such as practice standards [INLET PROTECTION – BLOCK & GRAVEL 850](#), [INLET PROTECTION – EXCAVATED DRAIN 855](#), [INLET PROTECTION – FABRIC DROP 860](#) or [INLET PROTECTION – GRAVEL & WIRE MESH 861](#).

CRITERIA

The drainage area to each straw bale barrier inlet protection shall be one acre or less.

The inside edge of the bales shall be a maximum of 2 feet from the edge of the inlet.

Straw bale barrier inlet protection shall be installed prior to the storm sewer system becoming functional.

Filter fabric may be added to the upstream side of the straw bales to enhance sediment removal. The fabric shall meet the requirements as shown in material specification [592 GEOTEXTILE](#), Table 1 or 2, Class 1 with an AOS of at least 30 for non-woven and 50 for woven. The choice to use filter fabric must also consider the larger ponding area that will result.

CONSIDERATIONS

In developing areas, installation of streets and storm sewer networks usually occur before the construction of homes, businesses or other developments. During this, and subsequent phases of construction, unprotected soil is susceptible to erosion. Storm sewers that are operational before their drainage areas are stabilized often carry large amounts of sediment to lakes, detention ponds, streams, or other natural or constructed drainageways. As a result, the water quality of the receiving body of water is detrimentally affected. In cases of extreme sediment loading, the storm sewer may clog completely or lose a major portion of its capacity. To avoid these problems, it is necessary to prevent sediment from entering the system at the inlets.

Storm drain inlet protection consists of several types of inlet filters and traps. Each type differs in application dependant upon site conditions and type

of inlet. Not all designs are appropriate in all cases. The user must carefully select a design suitable for the needs and site conditions.

Straw bale inlet protection should be considered for trapping sediment where sheet and rill erosion is occurring in small, relatively flat drainage areas. Straw bale inlet protection should not be used in areas of concentrated flow.

At the time storm sewer inlet and associated appurtenances become operational, areas adjacent to the structures are most likely at final grade or will not be altered for extended periods. This is the time when practice standard [TEMPORARY SEEDING 965](#) and other appropriate controls should be implemented to reduce soil erosion.

Based on field observations in Illinois and other states, straw barriers have not been as effective as a sediment control measure as they could be. There are four major reasons for this. First, improper use of straw bales has been a major problem. Straw bale barriers have been used in drainageways where high water velocities and/or volumes have destroyed them or significantly impaired their effectiveness. Second, improper placement and installation of the barriers, such as staking the bales directly to the ground with no soil seal or entrenchment, has allowed undercutting and flow around the ends. This has resulted in additions of, rather than removal of, sediment from runoff waters. Third, inadequate inspection and maintenance lowers the effectiveness of these barriers. Fourth, because straw bales decompose in the presence of moisture, they have a very limited life span.

Runoff from areas larger than one acre should be routed through a properly designed practice such as [IMPOUNDMENT STRUCTURE - ROUTED 842](#), or [TEMPORARY SEDIMENT TRAP 960](#).

PLANS AND SPECIFICATIONS

Plans and specifications for installing straw bale barrier inlet protection shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

1. Inlet location.
2. The depth of trench required to bed the bales
3. The method(s) required to anchor the bales.
4. Filter fabric specifications if used.

All plans shall include the installation, inspection and maintenance schedules with the responsible party clearly identified.

Standard drawing [INLET PROTECTION - STRAW BALE BARRIER PLAN IL-563](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

Straw bale barrier inlet protection shall be inspected after every runoff producing rain and repairs made as needed.

Close attention shall be paid to the repair of damaged bales, end runs and undercutting beneath bales.

Necessary repairs to the barrier or replacement of bales shall be accomplished promptly.

Sediment shall be removed and the barrier restored to its original dimensions when the sediment has accumulated to one-half the barrier height. Removed sediment shall be deposited in a suitable area in such a manner that it will not erode.

When the contributing drainage area has been adequately stabilized, remove all materials and any unstable soil, and either salvage or dispose of it properly. Bring the disturbed area to proper grade, then smooth and compact it. Appropriately stabilize all bare areas around the inlet.

PRACTICE STANDARD

LAND GRADING

(acre)
CODE 865

(Source: NC Erosion and Sediment Control Planning and Design Manual)

DEFINITION

Reshaping the ground surface to planned grades as determined by engineering survey evaluation and layout.

PURPOSE

The purposes of this practice are to provide suitable topography for buildings, facilities, and other land uses, to control surface runoff, and to minimize soil erosion and sedimentation both during and after construction.

CONDITIONS WHERE PRACTICE APPLIES

This practice is applicable where grading to a planned elevation is necessary and practical for the proposed development of a site and for proper operation of sedimentation control practices.

CRITERIA

The grading plan and installation shall be based upon adequate surveys and

investigations. The plan is to show the location, slope, cut, fill, and finish elevations of surfaces to be graded. It will also show the auxiliary practices for safe conveyance of runoff water, slope stabilization, soil erosion and sediment control, and stormwater management. These practices may include but are not limited to retaining walls, grass-lined swales, grade stabilization structures, lined ditches, sediment basins, detention ponds, diversions and surface and subsurface drains. The practices may be temporary or permanent, depending upon the need after construction is completed.

The development and establishment of the plan shall incorporate the following, as appropriate:

1. The cut face of the excavation, which is to be vegetated, shall be two horizontal to one vertical (2:1) or flatter. Cut slopes of materials not to be vegetated shall be at or below the safe angle of repose for the materials encountered. For maintenance reasons 4:1 or flatter

- slopes are preferable. Slopes steeper than 2:1 shall require special design and stabilization considerations that shall be adequately shown on the plans.
2. The permanent exposed faces of fills shall be two horizontal to one vertical (2:1) or flatter. For slope maintenance, 4:1 or flatter is recommended. Slopes exceeding 2:1 shall require special design and stabilization considerations that shall be adequately shown on the plans.
 3. Provisions shall be made to safely conduct surface water to storm drains or to suitable natural water courses and to prevent surface runoff from damaging the cut faces and fill slopes.
 4. Subsurface drainage shall be provided in areas having a high water table to intercept seepage that would affect building foundations, slope stability, or create undesirable wetness.
 5. Excavations shall not be made so close to property lines as to endanger the adjoining property without supporting and protecting such property from erosion, sliding, settling, or cracking.
 6. No fill shall be placed where it will slide or wash upon the premises of another, or so placed adjacent to the bank of a channel as to create bank failure or decrease the natural carrying capacity of the stream. At a minimum, a setback of 25 feet should be provided as a buffer to sensitive areas.
 7. Fills shall consist of material from cut areas, borrow pits, or other approved sources. Fill material shall be free of brush, rubbish, rocks, logs, stumps, building debris, and other objectionable material. It should be free of stones over two inches in diameter where compacted by hand or mechanical tampers or over eight inches in diameter where compacted by rollers or other equipment. Frozen material shall not be placed in the fill nor shall the fill material be placed on a frozen foundation.
 8. Diversions shall be provided whenever the vertical interval of any slope exceeds 20 feet. Diversions shall be located to divide the slope face as equally as possible and shall convey the water to a stable outlet. Soils, seeps, rock outcrops, etc., shall also be taken into consideration when designing diversions.
 - a. Diversions shall be a minimum bottom width of six feet to provide for maintenance.
 - b. Diversions shall be designed with cut slope of 6:1 or flatter to the toe of the upper slope and with a minimum of one foot in depth. The gradient to the outlet shall be between 2% and 3%, unless accompanied by appropriate design and computations.
 - c. The flow length within a diversion shall not exceed 800 feet unless accompanied by an appropriate design and computations. See practice standards [DIVERSION 815](#), [DIVERSION DIKE 820](#) or [TEMPORARY DIVERSION 955](#).
 9. Surface water shall be diverted from the face of all cut and fill slopes by the use of diversions, ditches and waterways or conveyed downslope by the use of a designed structure, except where:
 - a. The face of the slope is or shall be stabilized and the face of all graded slopes shall be protected from surface runoff until they are stabilized.

- b. The face of the slope shall not be subject to any concentrated flows of surface water such as from natural drainageways, graded waterways, downspouts, etc.
 - c. The face of the slope shall be protected by special erosion control materials, sod, gravel, riprap, or other stabilization method.
10. Cut slopes occurring in ripable rock shall be serrated. These serrations shall be made with conventional equipment as the excavation is made. Each step or serration shall be constructed on the contour and will have steps cut at nominal two-foot intervals with nominal three-foot horizontal shelves. These steps will vary depending on the slope ratio or the cut slope. These steps will weather and act to hold moisture, lime, fertilizer and seed thus producing a much quicker and longer lived vegetative cover and better slope stabilization. Overland flow shall be diverted from the top of all serrated cut slopes and carried to a suitable outlet.
 11. Stockpiles, borrow areas, and spoil areas shall be shown on the plans and shall be subject to the provision of this standard.
 12. All disturbed areas shall be stabilized in accordance with the practice standards [MULCHING 875](#), [PERMANENT VEGETATION 880](#) or [TEMPORARY SEEDING 965](#), as appropriate.
 13. Use slope breaks, such as diversions or benches, as appropriate, to reduce the length of cut-and-fill slope to limit sheet and rill erosion and prevent gullyng. A spacing guide follows.

		Horizontal Distance (ft.)
Steep Slopes	2:1	20
	3:1	35
	4:1	45
Long Slopes	15-25%	50
	10-15%	80
	6-10%	125
	3-6%	200
	<3%	300

CONSIDERATIONS

Fitting a proposed development to the natural configurations of an existing landscape reduces the need for some erosion and sediment control measures. It may also result in a more desirable and less costly development.

Before grading begins, decisions must be made on the steepness of cut-and-fill slopes, how they will be protected from runoff, how they will be stabilized, and how they will be maintained. The grading plan establishes drainage areas, directs drainage patterns, and affects runoff velocities.

The grading plan forms the basis of the erosion and sediment control plan. Key considerations that affect erosion and sedimentation include deciding which slopes are to be graded, when the work will start and stop, the percent and length of finished slopes, where and how excess material will be disposed of, and where fill is needed.

Leaving undisturbed temporary and permanent buffer zones in the grading operation may provide an effective and low-cost erosion control measure that will help reduce runoff velocity and volume and off-site sedimentation. In developing the grading plan, always

consider how to take advantage of undisturbed water disposal outlets before storm drains or other constructed outlets are installed.

PLANS AND SPECIFICATIONS

Plans and specifications for land grading shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

1. The finished land slope grade and direction of land slope.
2. Location of other related structures, e.g., drains, curbs, etc.
3. Topsoil stockpile location.
4. Borrow areas if needed.

All plans shall include the installation, inspection, and maintenance schedules with the responsible party identified.

OPERATION AND MAINTENANCE

Periodically check all graded areas and the supporting erosion and sediment control practices, especially after heavy rainfalls. Promptly remove all sediment from diversions, sediment trapping practices and other water-disposal practices. If washouts or breaks occur, repair them immediately. Prompt maintenance of small, eroded areas before they become significant gullies is an essential part of an effective erosion and sediment control plan.

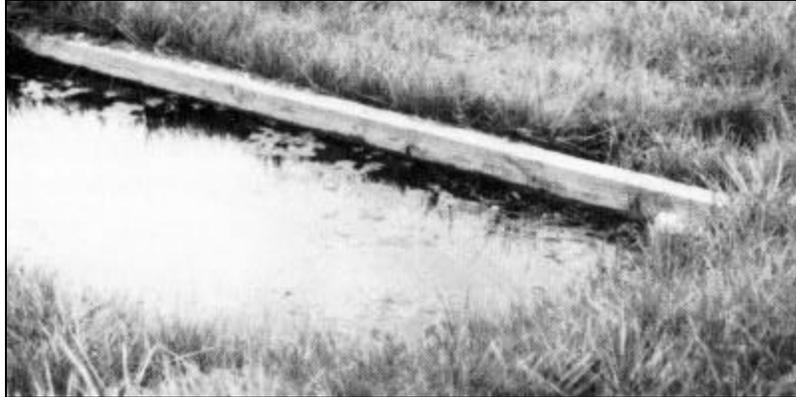

NRCS IL February 1994

urbst865.doc

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

LEVEL SPREADER

(no.)
CODE 870

(Source: VA Erosion and Sediment Control Handbook)

DEFINITION

A device used to disperse concentrated runoff uniformly over the ground surface as sheet flow.

PURPOSE

The purpose of this practice is to convert concentrated, potentially erosive flow to sheet flow and release it uniformly over a stabilized area or filter strip. The resultant sheet flow enhances pollutant filtering and runoff infiltration and reduces the potential for erosion.

CONDITIONS WHERE PRACTICE APPLIES

The principal application of a level spreader is to convey runoff from impervious surfaces, such as parking lots or roadways, uniformly onto vegetated filter strips. Level spreaders can also be applied as outlets for diversion structures. Level spreaders are appropriate and/or necessary under the following conditions:

1. Where runoff from an impervious

surface is uneven and/or runoff is released as concentrated flow, such as through curb cuts or roof downspouts

2. At the ends of diversions
3. Where the runoff water will not re-concentrate after release from the level spreader until it reaches an outlet designed for concentrated flow
4. Where sediment-free storm runoff can be released in sheet flow down a stabilized slope without causing erosion
5. Where the lip of the level spreader can be constructed in undisturbed soil
6. Where there will be no traffic over the spreader

CRITERIA

Criteria for level spreader design can vary greatly depending on the application. For this reason, two sets of criteria are specified for several of the factors that follow.

For impervious surface runoff applications:

The capacity for the level spreader is determined in the design of the filter strip to which it discharges (see practice standard [FILTER STRIP 835](#)).

The spreader shall run linearly along the entire width of the filter strip to which it discharges. In most cases, the spreader will be the same width as the contributing impervious surface. The ends of the spreader shall be tied into higher ground to prevent flow around the spreader.

The minimum depth shall be 6 inches and the minimum width shall be 6 feet for the lower side slope. Side slopes shall be 2:1 (horizontal to vertical) or flatter.

The grade of the spreader shall be 0%.

The discharge area shall meet the requirements of practice standard [FILTER STRIP 835](#).

For diversion outlet applications:

The capacity of the spreader shall be determined using the peak flow from the 10-year frequency, 24-hour duration storm. The drainage area shall be restricted so that maximum flows into the spreader will not exceed 30 cfs.

Spreader dimensions: Select the length and depth of the spreader from the table below. The length dimension is parallel to the diversion.

Design Flow (cfs)	Minimum Depth (ft)	Minimum Length (ft)
0-10	0.5	10
10-20	0.6	20
20-30	0.7	30

The minimum width of the spreader shall be 6 feet for the lower side slope. Side slopes shall be 2:1 (horizontal to vertical) or flatter.

Construct a 20 foot transition section in the diversion channel so the width of the channel will smoothly meet the width of the spreader to ensure uniform outflow.

The last 20 feet of the diversion channel shall provide a smooth transition from the channel grade to the level spreader and where possible, shall be less than or equal to 1%. The grade of the level spreader shall be 0%.

The outlet discharge area must be generally smooth and well vegetated with a maximum slope of 10%.

For all applications:

The spreader lip shall be constructed to a uniform height and zero grade over the length of the spreader. For design flows of 4 cfs or greater, a rigid lip of non-erodible material, such as pressure-treated timbers or concrete curbing, shall be used. For flows less than 4 cfs, a vegetated lip may be used. The spreader lip shall be constructed on undisturbed soil.

When using a vegetated lip it shall be protected with an erosion control blanket to prevent erosion and allow the vegetation to become established. The erosion control blanket for a vegetated lip shall meet the requirements of

practice standard [EROSION BLANKET 830](#). The blanket shall be a minimum of 4 feet wide extending a minimum of 1 foot downstream over the level lip. The blanket shall be secured with heavy duty staples and the downstream and upstream edges shall be buried at least 6 inches deep in a vertical trench.

When using a rigid lip it shall be entrenched at least 4 inches below existing ground and securely anchored to prevent displacement. An apron of coarse aggregate meeting IDOT CA-1 or CA-3 gradation shall be placed to the top of the rigid lip and extend downslope at least 3 feet. A filter fabric shall be placed under the coarse aggregate. The filter fabric shall meet the requirements of material specification [592 GEOTEXTILE](#) Table 1 or 2, Class I, II, or IV.

Immediately after level spreader construction, seed and mulch the entire disturbed area of the spreader. Seeding shall meet the requirements of practice standard [PERMANENT VEGETATION 880](#) and mulching shall meet the requirements of practice standard [MULCHING 875](#).

CONSIDERATIONS

The level spreader is a relatively low-cost structure to:

1. Disperse impervious surface runoff uniformly to a filter strip or
2. Release small volumes of concentrated flow from diversions when conditions are suitable

To accomplish these purposes, particular care must be taken to construct the spreader lip completely level. Any depressions in the lip will

concentrate the flow, resulting in a loss of pollutant filtering effectiveness and/or erosion. Evaluate the outlet system to be sure that flow does not concentrate below the outlet.

For filter strip applications, the determination of whether a level spreader is needed should be based on how the runoff is entering the filter strip. If the runoff is concentrated by curb cuts, and particularly if a large area of impervious surface drains to one point, a level spreader is essential to achieve effective pollutant removal in the filter strip. A level spreader also is important if the filter strip is relatively steep in order to avoid erosion from concentrated runoff discharge. If the runoff is evenly distributed over the width of the impervious surface (e.g., a curbless, even-sloped road or parking lot), a level spreader may not be necessary.

When the level spreader is used as an outlet for temporary or permanent diversions and diversion dikes, runoff containing high sediment loads must be treated in a sediment trapping device such as practice standard [TEMPORARY SEDIMENT TRAP 960](#) or [IMPOUNDMENT STRUCTURE - ROUTED 842](#) before release into a level spreader.

PLANS AND SPECIFICATIONS

Plans and specifications for installing a level spreader shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

1. The spreader location
2. The length and width

3. For filter strip applications, plans for both the adjacent impervious surface and the filter strip, for diversion outlets, plans detailing the diversion structure and the adjacent outlet area
4. Lip details: vegetated or rigid
5. Stone gradation
6. Filter fabric specifications if used
7. Rigid lip material specifications if used
8. Erosion control blanket specifications if used
9. Seeding and mulching requirements

Virginia Department of Conservation and Recreation, Division of Soil and Water Conservation, 1992. Virginia Erosion and Sediment Control Handbook, 3rd ed., VA

NRCS IL January 1999

urbst870.doc

All plans shall include installation, inspection, and maintenance schedules with the responsible party identified.

Standard drawing [LEVEL SPREADER IL-570](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

Inspect level spreaders after every rainfall until vegetation is established, and promptly make needed repairs. After the area has been stabilized, make periodic inspections and maintain vegetation in a healthy, vigorous condition.

Verify that the level spreader is distributing flow evenly. If problems are noted, make appropriate modifications to ensure even flow distribution.

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

MULCHING

(acre or sq.ft.)
CODE 875

(Source: Kane-DuPage Soil and Water Conservation District)

DEFINITION

The application of plant residues and other suitable materials to the soil surface.

PURPOSE

The purposes of this practice are as follows:

1. To prevent erosion and prevent surface compaction or crusting by protecting the soil surface from raindrop impact and reducing the velocity of overland flow.
2. To foster the growth of vegetation by conserving available moisture and providing insulation against extreme heat and cold.
3. To improve the aesthetics of the site.
4. To control weeds.

CONDITIONS WHERE PRACTICE APPLIES

Temporary Mulches:

1. Areas that have been seeded to provide a temporary or permanent

seeding.

2. Areas that cannot be seeded because of the season of the year and need for soil surface protection.
3. For mud and dust control.
4. Provide protection during periods when construction or seeding cannot be done.

Permanent Mulches:

1. Used together with planting trees, shrubs, and other ground covers that do not provide adequate soil stabilization.
2. Used in lieu of vegetative planting for ornamental reasons or because the site is not suitable for vegetation.

CRITERIA

1. The choice of materials will be based on the type of soil to be protected, season and economics.
2. Prior to Application
 - a. Shape and grade, as required, the waterway, channel, slope, or other area to be protected.

- b. Remove all rocks, clods, or debris larger than 2 inches in diameter that will prevent contact between the mulch and the soil surface.
 - c. When open-weave nets are used, lime, fertilizer, and seed may be applied either before or after laying the net. When excelsior matting is used, these materials must be applied before the mat is laid.
3. Time of Application
- a. Immediately after seeding or planting by conventional method or hydroseeding. Can be applied with seeding as hydromulching.
 - b. Immediately after seedbed preparation when dormant seedings are to be made by seeding over the mulch.
 - c. When temporary erosion control is to be attained, mulch may be applied any time soil and site conditions are suitable for spreading and anchoring.
4. Application - Mulch materials shall be spread uniformly, by hand or machine. When spreading straw mulch by hand, divide the area to be mulched into approximately 1,000 sq. ft. sections and place approximately 90 lbs. of straw in each section to facilitate uniform distribution.
5. Mulch Anchoring - Straw mulch shall be anchored immediately after spreading to prevent wind blow. One of the following methods of anchoring straw shall be used:
- a. Mulch anchoring tool - This is a tractor-drawn implement (mulch crimper, serrated straight disk, or dull farm disk) designed to punch mulch approximately 2 inches into the soil surface. This method

- provides maximum erosion control with straw. It is limited to use on slopes no steeper than 3:1, where equipment can operate safely. Machinery shall be operated on the contour.
- b. Liquid mulch binders - Application of liquid mulch binders and tackifiers should be heaviest at edges of areas and at crests of ridges and banks, to prevent wind blow. The remainder of the area should have binder applied uniformly. Binders may be applied after mulch is spread; however, it is recommended sprayed into the mulch as it is being blown onto the soil. Applying straw and binder together is the most effective method.

The following types of binders may be used:

- i. Asphalt - Any type of asphalt thin enough to be blown from spray equipment is satisfactory. Recommended for use are rapid curing (RC-70, RC-250, RC-800), medium curing (MC-250, MC-800) and emulsified asphalt (SS-1, MS-2, RS-1, and RS-2).
- ii. Synthetic Binders - Chemical binders may be used as recommended by the manufacturer to anchor mulch. These are expensive, and therefore, usually used in small areas or in residential areas where asphalt may be a problem.
- iii. Wood Fiber - Wood fiber hydroseeder slurries may be used to tack straw mulch.

This combination treatment is well suited to steep slopes, critical areas, and severe climate conditions.

- c. Mulch nettings - Lightweight, degradable, plastic, polyester, or paper nets may be stapled over the mulch according to manufacturer's recommendations.
- d. Peg and twine - Because it is labor-intensive, this method is feasible only in small areas where other methods cannot be used. Drive 8 to 10-inch wooden pegs to within 3 inches of the soil surface, every 4 feet in all directions. Stakes may be driven before or after straw is spread. Secure mulch by stretching twine between pegs in a criss-cross-within-a-square pattern. Turn twine 2 or more times around each peg.

Chemical Mulches - Chemical mulches may be used alone only in the following situations:

1. Where no other mulching material is available.
2. In conjunction with temporary seeding during the times when mulch is not required for that practice.

Note: Chemical mulches may be used to bind other mulches or with wood fiber in a hydroseeded slurry at any time. Manufacturer's recommendations for application of chemical mulches shall be followed.

Nets and Mats - Nets may be used alone on level areas, on slopes no steeper than 3:1, and in waterways.

When mulching is done in late fall or during June, July, and August, or where soil is highly erodible, nets should only be used in conjunction with an organic mulch such as straw.

When nets and organic mulch are used together, the net should be installed over the mulch except when the mulch is wood fiber. Wood fiber may be sprayed on top of the installed net.

Excelsior blankets are considered protective mulches and may be used alone on erodible soils and during all times of year.

Other products designed to control erosion shall conform to manufacturer's specification and should be applied in accordance with manufacturer's instructions provided those instructions are at least as stringent as this specification.

Laying the Net:

1. Start laying net from top of channel or top of slope and unroll downgrade. Always lay netting in the direction of water flow.
2. Allow to lie loosely on soil - do not stretch.
3. To secure net: Upslope ends of net should be buried in a slot or trench no less than 6 inches deep. Tamp earth firmly over net. Staple the net every 12 inches across the top end. Edges of net shall be stapled every 3 feet. Where 2 strips of net are laid side by side, the adjacent edges shall be overlapped 3 inches and stapled together.

Staples will be made of plain iron wire, No. 8 gauge or heavier, and will be 6 inches or more in length. Staples shall

be placed down the center of net strips at 3-foot intervals. DO NOT STRETCH net when applying staples.

Joining strips - Insert new roll of net in trench, as with upslope ends of net. Overlap the end of the previous roll 18 inches, turn under 6 inches, and staple across end of roll just below anchor slot and at the end of the turned-under net every 12 inches.

At bottom of slopes - Extend net out onto a level area before anchoring. Turn ends under 6 inches, and staple across end every 12 inches.

Check slots - On highly erodible soils and on slopes steeper than 4:1, erosion check slots should be made every 15 feet. Insert a fold of net into a 6-inch trench and tamp firmly. Staple at 12-inch intervals across the downstream portion of the net.

Rolling - After installation, stapling, and seeding, the net should be rolled to ensure firm contact between net and soil.

CONSIDERATIONS

1. A surface mulch is one of the most effective means of controlling runoff and erosion on disturbed lands.
2. The choice of materials for mulching shall be based on the type of soil to be protected, site conditions, season, and economics.
3. Organic mulch materials such as straw, wood chips, bark, and wood fiber have been found to be the most effective.
4. Chemical soil stabilizers or soil binders are not effective mulches when used alone. These materials

are useful to bind organic mulches together.

5. A variety of mulch nets, mats, or blankets are available to use as mulching or to hold the mulch in place. Netting and mats are especially helpful on critical areas such as waterways.

Organic Mulches:

Straw - The mulch most commonly used in conjunction with seeding. The recommended straw should come from oats, wheat, rye or barley, and may be spread by hand or machine. Straw can be windblown and should be anchored to stay in place.

Wood Chips - Suitable for areas that will not be closely mowed, and around ornamental plantings. Chips decompose slowly and do not require tacking. They should be treated with 12 pounds nitrogen per ton to prevent nutrient deficiency in plants. They also can be very inexpensive mulch if obtained from trees cleared on the site.

Bark Chips, Shredded Bark - By-products of timber processing. They are often used in landscaped plantings. Bark is also suitable mulch for areas planted to grasses and not closely mowed; and may be applied by hand or mechanically. Bark is not usually toxic to grasses or legumes, and additional nitrogen fertilizer is not required.

There are other organic materials that make excellent mulches but are only available locally or seasonally. Creative use of these materials can reduce costs.

Chemical Mulches and Soil Binders:

A wide range of synthetic, spray-on materials are marketed to stabilize and protect the soil surface. These are emulsions or dispersions of vinyl compounds, asphalt, rubber, or other substances which are mixed with water and applied to the soil. They may be used alone or may be used to tack wood fiber hydromulches or straw.

When used alone, chemical mulches do not have the capability to insulate the soil or retain soil moisture that organic mulches have. This soil protection is also damaged by traffic. Application of these mulches is usually more expensive than organic mulching, and the mulches decompose in 60-90 days.

Nets and Mats:

When used alone, netting does not retain soil moisture or modify soil temperature. It stabilizes the soil surface while grasses are being established, and is useful in grassed waterways and on slopes. Light netting may also be used to hold other mulches in place.

The most critical aspect of installing nets and mats is obtaining firm, continuous contact between the material and the soil. Without such contact, the material is useless and erosion occurs. It is important to use an adequate number of staples and to roll the material after laying it to ensure that the soil is protected.

Aggregate Cover - Gravel and crushed stone provide a long-term protection against erosion, particularly on short slopes. Before the gravel or crushed stone is applied it should be washed. If

vegetation is not desired, black polyethylene sheeting should be placed on the ground first to prevent seed germination and growth through the aggregate cover.

PLANS AND SPECIFICATIONS

Plans and specifications for applying mulch shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

1. Materials to be used.
2. How mulch will be anchored.
3. Location of different materials if more than one material is used on the site.

All plans shall include installation, inspection, and maintenance schedules with the responsible party identified.

OPERATION AND MAINTENANCE

All mulches should be inspected periodically, in particular after rainstorms, to check for rill erosion. Where erosion is observed, additional mulch should be applied. Nets should be inspected after rainstorms for dislocation or failure. If washouts or breakage occur, re-install netting as necessary after repairing damage to the slope. Inspections should occur until grasses are firmly established. Where mulch is used with ornamental plantings, inspect periodically throughout the year to determine if mulch is maintaining coverage of the soil surface; repair as needed.

NRCS IL December 1994

urbst875.doc

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

PERMANENT VEGETATION

(acre or sq.ft.)
CODE 880

(Source: USDA - Natural Resources Conservation Service - Illinois)

DEFINITION

Establishing permanent vegetative cover to stabilize disturbed or exposed areas.

PURPOSE

The purposes of this practice are to:

1. Permanently stabilize disturbed or exposed areas in a manner that adapts to site conditions and allows selection of the most appropriate plant materials.
2. Reduce erosion and sedimentation from such areas.
3. Create a landscape that enhances soil permeability and the filtering of runoff pollutants, while improving wildlife habitat.

CONDITIONS WHERE PRACTICE APPLIES

1. Disturbed areas where long-lived vegetative cover is needed to stabilize the soil.

2. Rough graded areas that will not be brought to final grade for a year or more.
3. Other areas where permanent cover is desired.

CRITERIA

Selection of plant materials

Selection of plant materials shall be based on climate, topography, soils, moisture conditions, land use, available light (shade tolerance), aesthetics, planned use of the area, and the degree of maintenance desired. All seed shall be of high quality and comply with Illinois Seed and Weed Laws.

See Tables A, B and C for selection of grasses, forbs, ground covers, and vines under different moisture and light conditions. These tables provide information for selected species that are generally commercially available and suitable for use in urban and agricultural settings. The native species presented represent those that are more tolerant of disturbed urban situations where this

practice would be applied. See the references given with the tables for information on additional species. The tables in this standard are not meant to be all-inclusive and the information in this standard can be applied to other species that may be desired or suitable for a given application. For trees and shrubs see practice standard [TREE AND SHRUB PLANTING 985](#). For manicured turf grass sod, see practice standard [SODDING 925](#).

Site Preparation

The site shall not be worked when frozen or saturated. Install necessary erosion and sediment control practices before seeding, and complete grading according to the approved plan. The grading plan shall utilize techniques and equipment that minimize soil compaction. If the final graded site consists of subsoil that may have been compacted by heavy equipment during grading activities, the subgrade shall be scarified to a depth of at least four inches by chisel plowing, disking or harrowing. This practice will create at least limited pore space for water and root penetration and bonding of the topsoil and the subsoil.

After the grading operation, spread topsoil where needed following practice standard [TOPSOILING 981](#). Topsoil shall meet criteria in material specification [804 MATERIAL FOR TOPSOILING](#).

Seedbed preparation

If needed based upon soil conditions and desired vegetation type, incorporate the lime and fertilizer into the soil with a disk harrow, springtooth harrow, or similar tools to a depth of at least 3

inches. On sloping areas the final operation shall be on the contour.

Prior to seeding or planting, the seedbed shall be relatively free of all weeds ($\geq 80\%$ weed free), stones, roots, sticks, rivulets, gullies, crusting and caking, or other debris which may interfere with seeding or planting operations or plant establishment.

The seedbed shall not be worked when frozen or saturated. Prior to seeding or planting the surface shall be disked or raked to a depth of 2-3 inches either by hand or mechanical means to create a smooth uniform seedbed. This operation should result in a seedbed comprised of soil aggregates ranging from fine to coarse, with none larger than two inches in diameter.

In areas that have not been regraded, which have grown up in weeds, or to be no-till seeded, a herbicide application may be necessary to reduce competition with the desired vegetation. An approved herbicide may be used to treat such areas to kill all existing vegetation. Herbicide application shall be done at least 15 days prior to seeding or planting.

Fertilization

Fertilizer or lime is generally not recommended for native vegetation establishment unless soil tests indicate $\text{pH} < 5.5$, $\text{P} < 15 \text{ lb./ac.}$, or $\text{K} < 150 \text{ lb./ac.}$ If levels are below this, apply lime and fertilizer according to a soil test and the needs of the vegetation selected.

Seed

All legumes shall be inoculated with the

proper inoculant prior to seeding. Seeding rates given in Tables A and B are based upon Pure Live Seed (PLS).

Seed mixtures shall be selected according to site conditions and desired use and appearance. Other considerations include soil moisture condition, shade tolerance, mowing tolerance, winter hardiness, flooding tolerance, mature height, emergence time, and salt tolerance.

All seeds shall have the proper stratification and/or scarification to break seed dormancy for spring or early summer plantings. No treatments are needed for late summer, early fall, or dormant seeding.

Seeding

Seeding may be done by any of the following methods:

1. Conventional Drill

- a. Apply seed uniformly at a depth of 1/4 to 1/2 inch with a drill (band seed) or cultipacker seeder. On sloping land, seeding operations should be on the contour wherever possible.
- b. Apply mulch or erosion blanket following seeding as required.

2. Broadcast Seeding

- a. Cultipack or roll seedbed, then apply seed uniformly and cover to 1/4 to 1/2 inch depth with a cultipacker, or similar tool. Spinning disc type broadcasters equipped with an agitator are effective with native seed mixes. Often broadcasters require the use of a carrying agent such as oats or vermiculite. Attention

should be given to seed mixes with seeds of varying size and weight so that the seed remains effectively mixed during seeding operations.

- b. On sloping land, dragging, harrowing or cultipacking should be done on the contour to ensure seed-soil contact and reduce erosion.
- c. Apply mulch or erosion blanket following seeding as required.

3. Hydroseeding

- a. For areas to be hydroseeded, final seedbed preparation shall leave the soil surface in a slightly roughened condition.
- b. Lime and fertilizer shall be incorporated prior to seeding unless they are to be applied at the same time as the seed (applying lime with a hydroseeder may be abrasive to the equipment). Do not use hydrated lime in a slurry mix.
- c. A minimum of 1000 gallons of water per acre shall be used. The hydraulic seeding equipment shall include a pump rated and operated at no less than 100 gallons per minute and at no less than 100 pounds per square inch pressure. The tank shall have a mechanical agitator powerful enough to keep all materials in a uniform suspension in the water. Calibration of the hydraulic equipment shall be accurate.
- d. When seeding legumes, increase the recommended rate for inoculant four times for hydroseeding. If legume inoculant is added to a fertilizer and/or lime, seeding should be applied within 30 minutes.

- e. If seed and fertilizer are mixed together they should be seeded within 2 hours of mixing.

4. Dormant Seeding

Dormant seeding may be done between November 15 and March 15 by using conventional drill or broadcast methods.

If soil conditions are suitable during the dormant seeding period, prepare the seedbed and seed as indicated in this specification. Apply mulch or erosion blanket following seeding.

5. No-till

In some instances it may be desirable to sow seed into existing sod, a temporary cover crop, or natural vegetation. Drilling may be done after herbicide application to non-native sod or undesirable weeds such as Canada thistle. A rangeland type grass drill with a no-till attachment shall be used. Seeds should be drilled to the depth appropriate for the species, according to the supplier's recommendations.

The seeds of some plants require light to stimulate germination and growth. In situations with some of these species, particularly some native forbs, a combination of broadcasting and no-till drilling may be used. Grasses should be drilled first, followed by broadcasting of the desired forbs.

Plugs and Rootstock

Some plants cannot be grown readily from seed and must be planted vegetatively (see Table A). Plugs are young plants that are grown in a nursery or greenhouse for transplant. Rootstock may consist of fragments of horizontal

stems or roots that include at least one node (joint).

1. Plugs

Plugs shall be planted in designated areas according to site plans and the recommendations of the supplier for that species. Attention should be given to soil moisture, anticipated flooding, shade, and other factors.

- a. Plugs shall be planted in a hole dug with a trowel, spade, planting bar, or suitable instrument such that the hole is of a minimum diameter and depth to accommodate the plug, with its roots, without damage.
- b. The soil excavated from the planting hole should be used to backfill around the plant and lightly packed to secure the roots in the soil.
- c. Plugs shall be watered upon completion of planting enough to keep soil moist but not saturated.
- d. If planting is delayed more than six hours after delivery, store plugs in the shade, protect from the weather and mechanical damage, and keep them moist and cool. All plugs should be planted within 24 hours of delivery.
- e. Plugs shall be obtained from a reputable nursery or grown from seed. Plugs shall not be collected from wild populations of plants.

2. Rootstock

Plant tubers and other rootstock into a properly prepared area according to the following and in accordance with the

suppliers recommendations for that species.

- a. Tubers and rootstock should be freshly dug before planting. If planting is delayed, protect material from weather and mechanical damage, and keep moist and cool. Do not use materials that have been in cold storage more than 45 days.
- b. Holes for planting rootstock shall be dug in locations shown on plans or as adjusted in the field.
- c. Holes shall be dug with a trowel, spade, planting bar or other suitable instrument, such that holes are of a minimum depth and diameter to accommodate the tuber or rootstock without damage.
- d. Rootstock shall be obtained from a reputable nursery or grown from seed. Rootstock shall not be collected from wild populations of plants.

Ground Covers

Most shrub and vine type ground covers are available as bare root stock, balled and burlapped, or in containers or pots. Many ground covers and vines perform best when planted in the spring. Container-grown plants can be planted throughout the growing season if adequate water is provided.

Ground covers and vines are plants that naturally grow very close together and close to the ground or climbing over other plants. This can cause severe competition for space, nutrients and water. Soil for ground covers should be well-prepared. A well-drained soil high in organic matter is best. If the area to be planted is so large or difficult to

prepare due to steepness or rockiness that adding amendments to the soil as a whole would be impractical, organic matter and fertilizer may be added to each planting hole.

Lime and fertilize according to soil test, if needed. If no soil test is available and the soil is believed to be deficient, add 30 lbs. of 10-10-10 fertilizer and 100 lbs. of ground agricultural limestone per 1000 square feet. Incorporate into the top 4 to 6 inches of the soil.

When planting individual plants, prepare a hole slightly larger than the container or ball and deep enough that the roots can extend to the bottom. Most ground covers should be planted $\frac{1}{2}$ " to 1" deeper than they have grown in the pot or container.

Mulching/Erosion Blanket

All permanent seedings shall be mulched upon completion of seed application or planting. Refer to practice standard [MULCHING 875](#). Erosion blanket should be substituted for mulch on steep slopes (10% slope or greater) or wherever highly erosive conditions exist (e.g. in drainage swales or waterbody shorelines). Refer to practice standard [EROSION BLANKET 830](#). When planting plugs and tubers, particularly in wetland plantings, mulch or erosion blanket should NOT be used except in specific areas with erosive conditions. When planting ground covers it may be advantageous to apply mulch or erosion blanket prior to planting. Plants should then be tucked into the soil through slits or holes. In all cases, planting should be done in a staggered pattern to minimize erosion.

CONSIDERATIONS

Where feasible, deep-rooted native species are preferred because of their abilities to enhance soil permeability and pollutant filtering and their reduced needs for fertilizer, herbicides, irrigation, and mowing. Care also should be taken to avoid non-native aggressive species that could spread beyond the site boundaries.

The best time for seeding depends upon the species; there is no single best time to seed. There are certain groups of species which do best fall planted and are compromised by spring seeding. There are other groups of species that do best spring planted and are compromised by fall seeding. Some species are not tolerant of nurse or temporary cover crops while others benefit by them. Some species are difficult to establish in the field from seed and are far more practical to install as plugs.

Some species require light for germination and are thus less successful if drilled into the soil, while others require burial to have successful germination. Broadcasting is generally favored for native species for this reason, and so the plants do not become established in unnatural looking rows. A temporary cover crop may be necessary to hold soil until permanent vegetation becomes established. See practice standard [TEMPORARY SEEDING 965](#).

Using an intact native soil is the most desirable situation, but in most cases stabilization is needed because of earthwork activities. In many instances, the topsoil may have been removed

and/or stockpiled during earthwork activities.

Evaluate the capabilities and limitations of the soil to be seeded or planted and the desired use and appearance of the area. Special attention needs to be given to soil pH, texture, internal water movement, moisture regime, steepness, and stability in order to plan the appropriate treatment.

PLANS AND SPECIFICATIONS

The plans and specifications for seeding or planting and mulching shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

1. Seed mixtures and rates or plant species and density.
2. Site preparation methods.
3. Fertilization rates and methods of application.
4. Seeding or planting methods.
5. Seeding or planting periods.
6. Mulching or erosion blanket materials and application rates.

All plans shall include the installation, inspection and maintenance schedules with the responsible party identified.

OPERATION AND MAINTENANCE

High-maintenance areas are mowed frequently, fertilized and pesticide treated regularly, and either (1) receive intensive use (e.g., athletic fields or golf courses) or (2) require maintenance to a particular aesthetic standard (e.g., home lawns). Grasses or ground covers used for these situations are long-lived perennials that form a tight sod and are

fine-leaved in appearance. They must be well adapted to the geographic area where they are planted and able to endure the stress of frequent mowing. Sites where high-maintenance vegetative cover is commonly utilized include homes, industrial parks, schools, churches, and active recreational areas.

High-maintenance seedings should be fertilized one year after planting to strengthen the plants and insure proper stand density. The following recommendations may be used:

1. For grass only stands, apply 200 lbs./acre (5 lbs/1000 sq. ft.) of 27-3-3, or equivalent.
2. For grass-legume or pure legume stands, apply 500 lbs/ac. (12 lbs./1000 sq. ft.) of 10-20-20, or equivalent.
3. The best time to apply fertilizer is between March 1 and May 30 or August 1 and September 30.

Do not mow high-maintenance turf seedings until the stand is at least 6 inches tall. Do not mow closer than 3 inches during the year of establishment.

In areas adjacent to waterbodies and wetlands, fertilizer should be used sparingly to minimize runoff of nutrients causing undesired growth of aquatic plants (eutrophication).

Low-maintenance areas are mowed infrequently or not at all, and do not receive lime, pesticide or fertilizer on a regular basis. Plants must persist with little maintenance over long periods of time. Native grass, forb, and legume mixtures are favored for these sites because they are deep-rooted and can add nutrients to the soil. Legumes in particular are a source of soil nitrogen.

Mixed stands are more resistant to adverse conditions. Sites suitable for low-maintenance vegetation include steep slopes, stream or channel banks, lake shorelines, stormwater drainage and detention facilities, office campuses, low-density residential properties, some commercial properties and areas adjacent to roadways.

Native plants typically do not require fertilization to become established. Experience in prairie restoration suggests that fertilizing adds to weed problems and promotes undesirable species. For this reason, conventional fertilizing is not recommended for native plantings.

Low-maintenance stands should be mowed only as needed to control weeds. Native plantings should be mowed to control weeds prior to August 15 during the establishment period (2-3 years). Mowing should be done before undesirable weeds set seed. Keep mowing height above the height of the seeded plants (6-12 inches).

Prescribed burning is the preferred maintenance technique for native prairie vegetation. Burns should be performed after the establishment period (2-3 years) on a 2-3 year rotational basis to control invasive weeds and to encourage a balance between grass and forb species. Less-frequent burning may be appropriate once the prairie is well established.

Goose or other nuisance wildlife control may be needed on some plantings. For example, plantings (plants, rootstock or seed) of native wetland plants must be protected from depredation by Canada geese. Goose exclosures constructed of fence posts and "chicken wire" netting

is usually recommended during the first year of establishment.

Vine and shrub type ground covers may need hand weeding until the area is well covered.

For ground covers and vines, prune old growth in the spring as needed to improve appearance and promote growth. If pruning is desired, it should be done every year rather than when the plants have developed into an overgrown state.

High and low maintenance areas

Vegetation cannot be expected to provide erosion control cover and prevent soil slippage on a soil that is not stable due to its structure, water movement, or excessive slope.

The operation of equipment is restricted and may be unsafe on slopes steeper than 3:1. Where steepness prohibits the use of farm machinery, seedbed preparation, fertilization, and seeding or planting may need to be done by hand.

Moisture is essential for seed germination and seedling establishment. Supplemental irrigation can be very helpful in assuring adequate stands in dry seasons or to speed development of full cover.

Protect the planted area from human, animal and vehicular traffic until the stand is adequately established.

Inspect all planted areas for failures and make necessary repairs, replacements, reseedings, and mulching within the planting season, if possible. If a stand has less than 70% ground cover, re-evaluate the choice of plant materials, quantities of lime and fertilizer, seeding

or planting methods, time of seeding or planting and available light and moisture. Re-establish the stand with modifications based on the evaluation.

After initial planting and/or seeding, irrigate to keep the seedbed moist (not wet) for at least 7 to 10 days after seeding depending on conditions. This may require watering daily the first week, especially during hot weather, and less frequently thereafter. Water application rates and delivery must be carefully controlled to prevent runoff and erosion. Inadequate or excessive amounts of water can be more harmful than no supplemental water. Irrigation is seldom needed for low-maintenance seedings made at the appropriate time of the year.

Herbicides may also be used for weed control. Apply all herbicides according to rates specified on the label.

Table A. Grass, forb, and sedge species for low maintenance areas.

Species ¹	Common name	Native	Moisture	Sunlight	Seeding rate ²	Aggressive	Salt tolerance	Seeds/oz. ³	Recommended planting method
GRASSES									
Agrostis alba	red top	N	mesic-wet	full-partial	.5-1.0	N	High	312000	seed
Andropogon gerardi	big blue stem	Y	mesic	full	2.0-5.0	N	No consensus	8200-10000	seed
Avena sativa	oats	N	mesic-dry	full	30-50	N	Moderate		seed
Bouteloua curtipendula	side oats grama	Y	mesic-dry	full	5	N	Low	6000-8000	seed
Bromus inermis	smooth brome	N	mesic-dry	full	24	Y	High	8500	seed
Bromus pubescens	woodland brome	Y	mesic	shade-partial	0.031	N	Low to Moderate	70875	seed
Calamagrostis canadensis	blue joint grass	Y	wet	full	.03-.25	N	Low	95000-280000	transplants (plugs)
Cinna arundinacea	common wood reed	Y	mesic	shade-partial	0.1-1.0	N	Low to Moderate	56700	seed
Dactylus glomerata	orchard grass	N	mesic-wet	full-partial	4-8	N	High	41000	seed
Echinochloa crusgalli	barn yard grass	Y	mesic-wet	full-partial	.375-4.0	Y	High	31500	seed
Elymus canadensis	nodding wild rye	Y	mesic-wet	full-partial	.02-3.0	N	Low-Moderate	4200-5200	seed
Elymus virginicus	Virginia wild rye	Y	mesic-wet	full-partial	.06-1.0	N	No consensus	4200-4500	seed
Festuca elatior	tall fescue (many varieties)	N	mesic-dry	full-partial	10-30	N	Moderate to High	14000	seed
Festuca rubra	red fescue (many varieties)	N	mesic	full-partial	10-20	N	Moderate to High	38000	seed
Glyceria striata	fowl manna grass	Y	mesic-wet	full-partial	.05-1.0	N	Low to Moderate	113000-160000	seed
Hystrix patula	bottlebrush grass	Y	mesic	shade-partial	0.062	N	Low to Moderate	4700-7600	seed
Leersia oryzoides	rice cut grass	Y	wet	full-partial	.1-1.0	N	No consensus	34000-94000	seed, rhizomes
Lolium multiflorum	annual ryegrass	N	mesic-dry	full-partial	10-30	N	Moderate to High	14000	seed
Lolium perenne	perennial ryegrass	N	mesic-dry	full-partial	10-30	N	Moderate to High	14000	seed
Panicum virgatum	switch grass	Y	mesic-wet	full-partial	.125-1.0	N	Moderate to High	14000-18000	seed
Phleum pratense	timothy	N	mesic	full-partial	.375-2.0	N	High	77000	seed
Schizachyrium scoparium	little blue stem	Y	dry	full	1.0-6.0	N	No consensus	8800-15000	seed
Sorghastrum nutans	Indian grass	Y	mesic	full	2.5-6.0	N	Moderate to High	8300	seed
Spartina pectinata	prairie cord grass	Y	wet	full-partial	.125-2.0	N	High	157500	rhizomes, transplants
Sporobolus heterolepis	prairie drop seed	Y	dry	full	.5	N	Low	14000-16000	seed
Zizania aquatica	wild rice	Y	wet	full	3	N	No consensus		seed
FORBS & GRAMINOIDS (grass-like)									
Acorus calamus	sweet flag	Y	6-20in. water	full-partial	.006-.25	N	No consensus	750-3300	rhizomes
Asclepias incarnata	swamp milkweed	Y	wet	full	.31	N	Moderate to High	4650	seed
Alisma subcordatum	water plantain	Y	0-6in. water	full	.06-.5	N	Moderate to High	60000-70000	seed
Aster leavis	smooth blue aster	Y	mesic-dry	full-partial	.02-.125	N	Low	48000-55000	seed
Aster lanceolatus	panicked aster	Y	mesic-wet	full-partial	.03-.06	N	Low to Moderate		seed
Aster novae-angliae	New England aster	Y	mesic-wet	full-partial	.03-.375	N	Low to Moderate	66000-70000	seed
Bidens cernua	nodding beggarsticks	Y	wet	full-partial	.25-.5	N	Moderate to High	14000-21000	seed
Bidens frondosa	common beggarsticks	Y	wet	full-partial	.125	Y	Moderate to High	28000	seed
Carex comosa	bristly sedge	Y	0-12in. water	full-partial	.125-.375	N	Low to Moderate	29000	transplants (plugs)
Carex cristatella	crested oval sedge	Y	wet	full-partial	.125	N	Low to Moderate	141750	fresh seed
Carex granularis	pale sedge	Y	wet	full-partial	.031	N	Low		fresh seed
Carex hystricina	porcupine sedge	Y	wet	full-partial	0.125	N	Low	29840	seed
Carex lanuginosa	wooly sedge	Y	wet	full	.125	N	Moderate to High	23625	seed
Carex scoparia	lance-fruited oval sedge	Y	wet	full-partial	0.125	N	Low	84000	seed
Carex stipata	awl-fruited sedge	Y	wet	full-partial	.125	N	Low to Moderate	35000	seed
Carex vulpinoidea	fox sedge	Y	wet	full-partial	.06-.5	N	Moderate	100000-141000	seed
Coreopsis tripteris	tall coreopsis	Y	mesic	full-partial	.25-.5	N	Low to Moderate	11500-14000	seed
Coreopsis palmata	prairie coreopsis	Y	mesic	full	.015-.5	N	Low	8800	seed
Echinacea pallida	pale purple cone flower	Y	mesic	full	.25-.5	N	Low	5100	seed
Eleocharis obtusa	blunt spike rush	Y	wet	full	.02-.4	N	Moderate		seed

Species ¹	Common name	Native	Moisture	Sunlight	Seeding rate ²	Aggressive	Salt tolerance	Seeds/oz. ³	Recommended planting method
Eleocharis smallii	creeping spike rush	Y	wet	full	.02-.4	N	Moderate		seed
Eupatorium maculatum	spotted joe pye weed	Y	wet	full	.06-2.0	N	Low to Moderate	85000-95000	seed
Eupatorium perfoliatum	common boneset	Y	wet	full	.06-.125	N	Low to Moderate	160000-200000	seed
Gentiana andrewsii	bottle gentian	Y	mesic-wet	full-partial	.015-.125		Low to Moderate	800000	seed
Geranium maculatum	wild geranium	Y	mesic	shade-partial	0.54	N	Low	350	seed
Helenium autumnale	sneezeweed	Y	wet	full-partial	.12-.5	N	Low to Moderate	130000	seed
Helianthus grosseserratus	sawtooth sunflower	Y	wet	full	.15-.31	Y	Moderate to High	15000	seed
Iris virginica	blue flag iris	Y	wet	full-partial	.06-.625	N	Low to Moderate	850-1000	rhizomes, transplants
Juncus effusus	common rush	Y	wet	full-partial	.37	N	Moderate to High		rhizomes
Juncus torreyi	Torrey's rush	Y	wet	full-partial	.006-.375	N	Moderate to High	70875	rhizomes
Liatris pycnostachya	prairie blazing star	Y	mesic-wet	full	.125	N	Low	11500	seed
Liatris spicata	marsh blazing star	Y	wet	full	.125	N	Low	11500	seed
Lotus corniculatus*	bird's foot trefoil	N	mesic	full	8	Y	High	25000	seed
Medicago sativa*	alfalfa	N	mesic	full	8	Y	Moderate to High	12500	seed
Lobelia cardinalis	cardinal flower	Y	wet	full-partial	.06	N	No consensus	300000-400000	seed
Monarda fistulosa	wild bergamot	Y	mesic	full-partial	.125-1.0	N	Moderate	75000-78000	seed
Petalostemum purpureum*	purple prairie clover	Y	mesic	full	.25	N	Low to Moderate	19000	seed
Phlox divaricata	woodland phlox	Y	mesic	shade-partial	0.13	N	Low	12500	seed
Polygonum amphibium	water smartweed	Y	0-20in. water	full	.5-1.5	N	No consensus		seed
Pycnanthemum virginianum	common mountain mint	Y	mesic-wet	full	.02-.06	N	No consensus	220000-284000	seed
Ratibida pinnata	yellow cone flower	Y	mesic	full	.125-.25	N	No consensus	27000-30000	seed
Rudbeckia hirta	black-eyed susan	Y	mesic	full-partial	.125-.5	N	Moderate	92000-100000	seed
Sagittaria latifolia	broadleaf arrowhead	Y	6-20in. water	full-partial	.06-.25	N	Moderate	56700	rhizomes, transplants
Scirpus acutus	hardstem bulrush	Y	0-36in. water	full	.06-.25	N	High	18000-30000	rhizomes
Scirpus americanus (pungens)	chairmaker's rush	Y	0-16.5in. water	full	.06-.125	N	Moderate to High		rhizomes
Scirpus fluviatilis	river bulrush	Y	0-30in. water	full-partial	.06-.125	N	Moderate to High	3375	rhizomes
Scirpus tabernaemontani (validus)	soft-stem bulrush	Y	12-20in. water	full	.06-.25	N	Moderate to High	31000-38000	rhizomes
Silphium laciniatum	compass plant	Y	mesic	full	.03-.19	N	Low to Moderate	655	seed
Silphium terebinthinaceum	prairie dock	Y	mesic-wet	full	.03-.19	N	Moderate	1050	seed
Smilacina racemosa	false solomon's seal	Y	mesic	shade-partial		N	Low to Moderate	900-1000	seed, transplants
Solidago gigantea	late goldenrod	Y	mesic-wet	full	.06-.3	N	Moderate to High	378000	seed
Sparganium eurycarpum	common burreed	Y	0-12in. water	full-partial	.2-.375	N	Low to Moderate	550	rhizomes
Tradescantia ohiensis	spiderwort	Y	mesic-dry	full-partial	.06-1.0	N	Low to Moderate	8000	seed
Trifolium hybridum*	alsike clover	N	mesic	full-partial	4-8	N	High	44000	seed
Trifolium pratense*	red clover	N	mesic	full-partial	4-8	N	Moderate to High	17000	seed
Verbena hastata	blue vervain	Y	wet	full	.015-.125	N	Moderate to High	93000-100000	seed
Vernonia fasciculata	common iron weed	Y	wet	full	.01-.19	N	No consensus	20000-24000	seed, transplants

¹ The nomenclature (plant names) used follow Kartesz (1994) which has been largely adopted as a national standard. Some commonly used synonyms are given in parentheses.

² All seeding rate information is pounds per acre and based upon Pure Live Seed (PLS). Seeding rates are given as ranges, since the actual seeding rate desired depends upon whether it is used as part of a mix or for a pure stand.

³ The seeds per ounce data is taken from supplier catalogues where available. Where no data was available or where large conflicts between sources existed this entry is blank.

* Legumes requiring proper inoculant.

Table B. High Maintenance (Turf Grass) Seed Mixtures.

Seed Mixture	Moisture Regime	Sun Light	Salt Tolerance	Seeding Rates (PLS)	
				lbs/ac.	lbs/1000sq ft
Kentucky blue grass use at least 3 varieties	dry-well drained	full-partial	moderate	88-130	2-3
Kentucky blue grass Red fescue	dry-well drained	full	moderate	110 44	2.5 1.0
Tall fescue (turf type)	dry-wet	full-shade	moderate	220-260	5-6

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

PERMEABLE PAVEMENT

(sq.ft.)
CODE 890

(Source: Conservation Design Forum)

DEFINITION

A pavement consisting of structural materials (e.g., concrete slabs, paving blocks or grids, or turf blocks) having regularly interspersed void areas. The voids are filled with pervious materials, such as vegetated soil, gravel or sand.

PURPOSE

The purpose of this practice is to reduce runoff and associated pollutants from low-volume traffic areas by providing a load bearing surface having adequate strength to accommodate vehicles while allowing infiltration of surface water and filtration of pollutants. This is accomplished by trapping a portion of rainfall in the pavement's voids and infiltrating it into the underlying soil.

CONDITIONS WHERE PRACTICE APPLIES

This practice applies where pavement is desirable or required for low-volume traffic areas.

This practice should be used with caution in areas underlain with highly permeable soils (i.e., surface sand or gravel) where infiltrated pollutants may reach groundwater without opportunity for attenuation.

The effects of subgrade compaction, freeze-thaw cycles and deicing and snow removal must be considered in determining the applicability of this practice.

Possible areas for use of these paving materials include:

1. Parking lots, especially fringe or overflow parking areas
2. Parking aprons, taxiways, blast pads, and runway shoulders at airports (heavier loads may demand use of reinforced grid systems)
3. Emergency stopping and parking lanes and vehicle cross-overs on divided highways
4. Off-street parking aprons in residential neighborhoods
5. Recreational vehicle camping area parking pads

6. Private roads, easement service roads, and fire lanes
7. Industrial storage yards and loading zones (heavier loads may demand use of reinforced grid systems)
8. Driveways for residential and light commercial use
9. Bike paths, walkways, patios, and swimming pool aprons
10. As an alternative to conventional paving in areas where tree protection and preservation is a concern

CRITERIA

Permeable pavement can infiltrate up to the first half inch of precipitation. Provisions must be made to handle the runoff from larger storms.

Permeable pavement system categories include:

1. Cast-in-place concrete slabs: Reinforced concrete slabs covering large areas are formed in place on the ground to be covered. The slab is suitable for heavy loads and has maximum resistance to movement caused by frost heave or settling.
2. Pre-cast concrete grids: Concrete paving units incorporating void areas, usually pre-cast in a concrete products plant and trucked to a job site for placement. These units have a higher percentage of permeable (i.e., grass) surface.
3. Modular unit pavers: Smaller pavers which may be clay bricks, granite sets or pre-cast concrete of various shapes. These pavers are monolithic units which do not have void areas incorporated in the blocks. They are installed on the base layer with pervious material placed in the gaps between units.

4. Geoweb: Although geoweb is primarily designed for soil reinforcement, they may be applicable as a permeable pavement.

The manufacturer's specifications shall be used to determine if the material to be used is suited for the intended purpose and for the gradation of the base course. The base course of granular material shall be at least 6 inches thick. Filter fabric shall be required between the compacted ground surface and the base course. The filter fabric shall meet the requirements of material specification [592 GEOTEXTILE](#) Table 1 or 2, Class I, II, or IV with AOS of 30 for woven and 50 for nonwoven.

CONSIDERATIONS

For stormwater quality as well as aesthetic purposes, it is recommended that the void areas in permeable pavement be filled with soil and planted with grass. Vegetation can improve infiltration and the physical filtering of runoff as well as reduce water volumes through long-term transpiration.

For parking lot applications, since permeable pavement with turf does not hold up well under frequent traffic, it is suggested to use permeable pavement only in the parking spaces and pave the traffic lanes in the normal fashion.

The runoff reduction effectiveness of permeable pavement is largely a function of the relative size of the openings in the pavement. Blocks with large openings, sometimes called turf blocks, are recommended. Conventional modular pavers that are grouted in place generally will not be very effective.

In areas where tree protection and preservation applies the protection of trees shall meet the requirements of practice standard [TREE PROTECTION 990](#).

is needed in plowing paving blocks or grids.

NRCS IL January 1999

urbst890.doc

PLANS AND SPECIFICATIONS

Plans and specifications for installing permeable pavement shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following:

1. Pavement location.
2. Paver thickness and type.
3. Base course thickness and gradation.
4. Filter fabric requirements.
5. Void material and dimensions.
6. Seeding requirements.

All plans shall include installation, inspection, and maintenance schedules with the responsible party identified.

OPERATION AND MAINTENANCE

Where turf is incorporated into these installations as the permeable surface medium, some turf maintenance will be necessary. However, fertilizers and deicing chemicals have adverse effects on concrete products in general, and the use of such chemicals should be restricted as much as possible. Deicing chemicals also adversely affect turf. Mowing is seldom required in areas of frequent traffic.

Cast-in-place installations, because they are monolithic and maintain a smooth surface, can be snow plowed provided the blade is set high enough to prevent damage to grass cover. Additional care

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

PORTABLE SEDIMENT TANK

(no.)
CODE 895

(Source: Kane-Dupage Soil and Water Conservation District)

DEFINITION

A compartmented container through which sediment-laden water is pumped to trap and retain the sediment.

PURPOSE

The purpose of this practice is to trap and retain sediment prior to pumping the water to drainageways, adjoining properties, and rights-of-way below the sediment tank site.

CONDITIONS WHERE PRACTICE APPLIES

A sediment tank is to be used on sites where excavations are deep and space is limited, such as urban construction, where direct discharge of sediment-laden water to stream and storm drainage systems is to be avoided. Also it is used where an excavation extends below the seasonal high water table causing a sump pump to be used.

CRITERIA

The portable sediment tank will be constructed with at least three equal baffled compartments. The inlet and outlet pipe will be a minimum diameter of 3 inches. The minimum storage volume of the tank shall be in cubic feet, calculated by multiplying 32 times the pump discharge in gallons per minute (GPM).

CONSIDERATIONS

The sediment tank should be located for ease of clean out and disposal of the trapped sediment, and to minimize the interference with construction activities and pedestrian traffic.

Portable sediment tanks should only be used when other sediment trapping practices cannot be installed due to lack of space or other reasons. This is due to their lack of efficiency and high labor requirements to remove the sediment.

PLANS AND SPECIFICATIONS

Plans and specifications for installing portable sediment tanks shall be in keeping with this standard and shall describe the requirements for applying the practice. The specifications will show the required storage volume of the tank.

All plans shall include installation, inspection, and maintenance schedules with the responsible party identified.

Standard drawing [IL-595 PORTABLE SEDIMENT TANK PLAN](#) may be used as the plan sheet. Other container designs can be used if the storage volume is adequate and approval is obtained from the local approving agency.

OPERATION AND MAINTENANCE

The tank shall be cleaned out when one-third of the storage volume is filled with sediment. All sediment collected in the tank shall be disposed of in an approved sediment trapping device such as practice standard [TEMPORARY SEDIMENT TRAP 960](#) or [IMPOUNDMENT STRUCTURE - ROUTED 842](#) or on the construction site or as approved by the engineer/inspector.

NRCS IL March 1994

urbst895.doc

RIGHT-OF-WAY DIVERSION

(no.)
CODE 900

(Source: MN Protecting Water Quality in Urban Areas)

DEFINITION

A ridge or ridge and channel constructed diagonally across a sloping road or utility right-of-way that is subject to erosion.

PURPOSE

The purpose of this practice is to limit the accumulation of erosive volumes of water by diverting surface runoff at predesigned intervals.

CONDITIONS WHERE PRACTICE APPLIES

Where runoff protection is needed to prevent erosion on sloping access right-of-ways or other long, narrow sloping areas generally less than 100 feet in width.

CRITERIA

The diversion ridge shall be constructed of compacted soil or coarse aggregate or a combination of both.

Coarse aggregate, if used, shall meet one of the following IDOT gradations: CA-1, CA-2, CA-3 or CA-4.

Height - The height shall be a minimum of 18 inches measured from the channel bottom to the ridge top for gravel diversions and 18 inches from ground surface to the ridge top for earth diversions.

Side slope - 2:1 or flatter, 3:1 or flatter where vehicles cross.

Base width of ridge - 6 feet minimum.

Length - The diversion should be constructed completely across the disturbed portion of the right-of-way.

The required spacing of diversions is shown below:

Average Land Slope (%)	Maximum Spacing (ft)
<5	125
5 to 10	100
10 to 20	75
20 to 35	50
>35	25

Grade and angle - The grade should be positive not to exceed 2%. A crossing angle of approximately 60 degrees is preferred.

Outlet - Diversions shall have stable outlets that are not subject to erosion. Site spacing may need to be adjusted for field conditions to utilize the most suitable outlet. Examples of stable outlets include practice standards [ROCK OUTLET PROTECTION 910](#), [LEVEL SPREADER 870](#), or [TEMPORARY SEDIMENT TRAP 960](#).

Concentrated flows should spread over the widest possible area after release. Flows with high sediment concentrations should pass through appropriate sediment trapping practices such as [IMPOUNDMENT STRUCTURE - ROUTED 842](#) or [TEMPORARY SEDIMENT TRAP 960](#).

CONSIDERATIONS

Construction of access roads, power lines, pipelines, and other similar installations often requires clearing long narrow rights-of-way over sloping terrain. Disturbance and compaction promotes gully formation in these cleared strips by increasing the volume and velocity of runoff. Gully formation may be especially severe in tire tracks and ruts. To prevent gulying, runoff can often be diverted across the width of the right-of-way to undisturbed areas by using small pre-designed diversions. Give special consideration to each individual outlet area, as well as to the cumulative effect of added diversions.

Generally earthen diversions are applicable where there will be little or no construction traffic within the right-of-way. Gravel structures are more applicable to road and other rights-of-ways where vehicular traffic is anticipated.

When earthen ridges are used, at all points where the ridge or channel will be crossed by heavy equipment the diversion should be protected according to requirements of the practice standard [STABILIZED CONSTRUCTION ENTRANCE 930](#).

PLANS AND SPECIFICATIONS

Plans and specifications for installing right-of-way diversions shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include:

1. Approximate location.
2. Minimum cross section and maximum grade.
3. Coarse aggregate gradation, if used.

All plans shall include installation, inspection, and maintenance schedules with the responsible party identified.

Standard drawing [IL-600 RIGHT-OF-WAY DIVERSION PLAN](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

Periodically inspect the right-of-way diversions for wear and after heavy rainfall for erosion damage. Remove sediment from the flow area and repair the dike. Check outlet areas and make timely repairs as needed. When permanent road drainage is established and the area above the temporary right-of-way diversions is permanently stabilized, remove the ridge and fill the channel to blend with the natural ground, and appropriately stabilize the disturbed area.

NRCS IL February 1994

urbst900.doc

ROCK CHECK DAM

(no.)
CODE 905

(Source: USDA Natural Resources Conservation Service - Illinois)

DEFINITION

A small rock dam constructed across a grassed swale or road ditch.

PURPOSE

The purposes of this practice are to reduce the velocity of concentrated stormwater flows, thereby reducing erosion of the swale or ditch, trap sediment generated from adjacent areas or the ditch itself and to increase infiltration when suitable soils are present.

CONDITIONS WHERE PRACTICE APPLIES

This practice, utilizing a combination of rock sizes, is limited to use in small grassed swales or open channels that drain 10 acres or less. It shall not be used in a perennial stream where protection of the flowing stream is the objective.

Some specific applications include:

1. Temporary ditches or swales that, because of their short time of

service, cannot receive a non-erodible lining but still need protection to reduce erosion

2. Permanent ditches or swales that cannot receive a permanent non-erodible lining for an extended period of time
3. Either temporary or permanent ditches or swales that need protection during the establishment of grass linings
4. An aid in the sediment trapping strategy for an active construction site. This practice is not a substitute for major perimeter trapping measures such as practice standard [TEMPORARY SEDIMENT TRAP 960](#).

CRITERIA

The drainage area of a ditch or swale being protected shall not exceed 2 acres when rock meeting IDOT CA-1, CA-2, CA-3 or CA-4 gradation is used alone and shall not exceed 10 acres when rock meeting IDOT RR-3 or RR-4 gradation and Quality Designation A is added on the downstream side of the dam.

The maximum height of the rock check dam shall be 3.0 feet. The top of the rock check dam shall be a minimum of 1.0 feet below the top of the ditch or swale.

The maximum spacing between the dams should be such that the toe of the upstream dam is at the same elevation as the top of the rock at the center of the downstream dam.

The rock check dams shall be placed such that the resultant ponding will not cause inconvenience or damage to adjacent areas or structures.

The center of the rock check dam shall be at least 6 inches lower than the sides. Hand or mechanical placement will be necessary to achieve complete coverage of the ditch or swale and to assure that the center of the dam is lower than the sides. Rock shall be placed according to construction specification [25 ROCKFILL](#) using Method 1 placement and Class III compaction.

CONSIDERATIONS

For added stability, the base of the rock check dam should be keyed into the soil to a depth of 6 inches.

Filter fabric may be used under the rock to provide a stable foundation and to facilitate removal of the rock. The filter fabric shall meet or exceed the requirements of material specification [592 GEOTEXTILE](#) Table 1 or 2, Class I, II or IV.

Rock check dams are effective in reducing flow velocity and thereby the potential for channel erosion. It is usually better to establish a protective

vegetative lining before flow is confined or to install a structural channel lining than to install rock check dams. Field experience has shown rock check dams to perform much more effectively than silt fences or straw bales in the effort to stabilize "wet-weather" ditches.

Rock check dams installed in grass-lined channels may kill the vegetative lining if submergence after rains is too long and/or siltation is excessive.

If temporary rock check dams are used in grass-lined channels that will be mowed, care should be taken to remove all the rock when the rock check dam is removed. This should include any rocks that have washed downstream.

Field experience has shown that many rock check dams are not constructed with the center lower than the sides forming a weir. Stormwater flows are then forced to the rock-soil interface, thereby promoting scour at that point and subsequent failure of the structure to perform its intended function.

PLANS AND SPECIFICATIONS

Plans and specifications for installing rock check dams shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following:

1. Location where the practice will be installed
2. Dimensions, elevations, and spacing between the dams
3. Rock gradation and quality
4. Fabric specification if used

All plans shall include installation, inspection, and maintenance schedules with the responsible person identified.

Standard drawing [ROCK CHECK DAM IL-605CA](#) or [IL-605R](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

On active construction sites, the rock check dams shall be inspected at least once every 7 days and within 24 hours of a rainfall of 0.5 inches or more. If any erosion has taken place around or below the rock check dam or if rocks have been dislodged, repairs shall be made to prevent further damage. Sediment shall be removed once it has accumulated to one-half the height of the rock check dam. The center of the rock check dam shall also be inspected periodically to insure that the center of the dam is lower than the sides.

Unless they will be incorporated into a permanent stormwater management control, rock check dams must be removed when their useful life has been completed. In temporary ditches and swales, rock check dams should be removed and the ditch filled in when they are no longer needed. In permanent structures, rock check dams should be removed when a permanent lining can be installed. In the case of grass-lined ditches, rock check dams should be removed when the grass has matured sufficiently to protect the ditch or swale. The area beneath the rock check dams should be seeded and mulched immediately after they are removed.

For rock check dams that are made a part of a permanent stormwater management control, regular

inspections should be made to see if any erosion has occurred around or below the dam and if any rock has been dislodged. Immediately make all needed repairs to prevent further damage. If sediment trapping is to be a continuing function of the rock check dam, the sediment shall be removed when it has accumulated to one-half the depth of the rock check dam.

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

ROCK OUTLET PROTECTION

(no.)
CODE 910

(Source: USDA - Natural Resources Conservation Service - Illinois)

DEFINITION

A section of rock protection placed at the outlet end of culverts, conduits, or channels.

PURPOSE

The purposes of this practice are to prevent scour erosion at stormwater outlets, to protect the outlet structure, and to minimize the potential for downstream erosion by reducing the velocity and energy of concentrated stormwater flows. The practice also reduces the effects of turbidity and sedimentation downstream.

CONDITIONS WHERE PRACTICE APPLIES

This practice applies where discharge velocities and energies at the outlets of culverts, conduits, or channels are sufficient to erode the receiving channel or area. This applies to:

1. Culvert outlets of all types.

2. Pipe conduits from all sediment basins, dry and wet basin detention storm water ponds.
3. New channels constructed as outlets for culverts and conduits.
4. Where outflows from conduits or channels do not exceed 10 fps.

The design of structurally lined aprons at the outlet of pipes and paved channel sections applies to the immediate area or reach below the pipe or channel and does not apply to continuous rock linings of channels or streams.

The design of rock outlet protection depends entirely on the location. Pipe outlets at the top of cuts or on slopes steeper than 10 percent cannot be protected by rock aprons or riprap sections due to reconcentration of flows and high velocities encountered after the flow leaves the apron.

CRITERIA

Tailwater depth - Depth of tailwater immediately below the pipe outlet must be determined for the design capacity of

the pipe. Manning's Equation may be used to determine tailwater depth. If the tailwater depth is less than half the diameter of the outlet pipe and the receiving stream is wide enough to accept divergence of the flow, it shall be classified as a Minimum Tailwater Condition. If the tailwater depth is greater than half the pipe diameter and the receiving stream will continue to confine the flow, it shall be classified as a Maximum Tailwater Condition. Pipes which outlet onto a flat area with no defined channel will be assumed to have a Minimum Tailwater Condition.

Apron length - Apron length (L_a) shall be determined from Table 2 according to the appropriate tailwater condition and velocity out of the conduits.

Apron width - When the pipe discharges directly into a well-defined channel, the apron shall extend across the channel bottom and up the channel banks to an elevation one foot above the maximum tailwater depth or to the top of the bank, whichever is less.

If the pipe discharges onto a flat area with no defined channels, the following criteria will be followed. Apron width will be 3 times the pipe diameter at the upstream location. The downstream width will be the pipe diameter plus the apron length for pipes with minimum tailwater conditions and the pipe diameter plus 0.4 times the apron length for pipes flowing under maximum tailwater conditions.

Bottom grade - The outlet protection apron shall be constructed with no slope (0.0% grade) along its length. There shall be no overfall at the end of the apron. The elevation of the downstream end of the apron shall be equal to the

elevation of the receiving channel or adjacent ground.

Alignment - Outlet protection apron shall be located so that there are no bends in the horizontal alignment.

Materials - Outlet protection may be done using rock riprap, concrete block or gabions.

Thickness - The maximum thickness of the riprap layer shall be 1.5 times the maximum stone diameter for d50 of 15 inches or less; and 1.2 times the maximum stone size for d50 greater than 15 inches. Table 1 lists some examples.

Stone quality - Stone for riprap shall consist of field stone or rough unhewn quarry stone. The stone shall be hard and angular and a quality that will not disintegrate on exposure to water or weathering. The specific gravity of the individual stones shall be at least 2.5.

The median size stone for riprap shall be determined from Tables 1 and 2 for the material specified for the tailwater condition present. The placement of the riprap shall conform to construction specification [61 LOOSE ROCK RIPRAP](#).

Recycled concrete equivalent may be used provided it has a density of at least 150 pounds per cubic foot, and does not have any exposed steel or reinforcing bars.

Filter Fabric - In all cases, filter fabric shall be placed between the riprap and the underlying soil to protect soil movement into and through the riprap. The material must meet or exceed requirements specified in material

specification [592 GEOTEXTILE](#), Table 1 or 2, Class I, II, or III.

Gabions - shall be made of hexagonal triple twist mesh with heavily galvanized steel wire. Gabions shall be fabricated in such a manner that the sides, ends, and lid can be assembled at the construction site into mats of the specified sizes. The mats shall be a minimum of 9 inches thick.

The area on which the gabion is to be installed shall be graded as shown on the drawings. Foundation conditions shall be the same as for placing rock riprap. Where required, a cut off may be needed to prevent undermining of the main gabion structure. Gabions shall meet the requirements for installation as shown in construction specification [64 WIRE MESH GABIONS](#).

CONSIDERATIONS

The outlets of channels, conduits and other structures are points of high erosion potential, because they frequently carry flows at velocities that exceed the allowable limit for the area downstream. To prevent scour and undermining, an outlet stabilization structure is needed to absorb the impact of the flow and reduce the velocity to non-erosive levels. A riprap-lined apron is the most commonly used practice for this purpose because of its relatively low cost and ease of installation. The riprap apron should be extended downstream until stable conditions are reached even though this may exceed the length calculated for design velocity control.

Riprap - stilling basins or plunge pools reduce flow velocity rapidly. They should be considered in lieu of aprons where overfalls exit at the ends of pipes

or where high flows would require excessive apron length. Consider other energy dissipaters such as concrete impact basins or paved outlet structures when conduits are flowing more than 10 fps. These will require a special design and Table 2 cannot be used.

PLANS AND SPECIFICATIONS

Plans and specification for installing rock outlet protection shall be in keeping with this standard and will describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following:

1. Location where the practice will be installed.
2. Dimensions of the practice.
3. Plan view, profile and cross section of each channel reach between the storm drain outlet under consideration and the existing publicly maintained system or the natural stream channel receiving the discharge flow.
4. Rock size and thickness.
5. Fabric specifications.

All plans shall include the installation, inspection, and maintenance schedules with the responsible party clearly identified.

Standard drawing [IL-610 PIPE OUTLET TO FLAT AREA](#) or [IL-611 PIPE OUTLET TO CHANNEL](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

Inspect riprap outlet structures after heavy rains to see if any erosion around or below the riprap has taken place or if stones have been dislodged.

Immediately make all needed repairs to prevent further damage.

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

SILT FENCE

(ft.)
CODE 920

(Source: USDA Natural Resources Conservation Service - Illinois)

DEFINITION

A temporary barrier of entrenched geotextile fabric (filter fabric) stretched across and attached to supporting posts used to intercept sediment-laden runoff from small drainage areas of disturbed soil.

PURPOSE

The purpose of this practice is to cause deposition of transported sediment load from sheet flows leaving disturbed areas

CONDITIONS WHERE PRACTICE APPLIES

A silt fence may be used subject to the following conditions:

1. The maximum allowable slope lengths contributing runoff to a silt fence are listed in the following table:

Slope (%)	Maximum Spacing (ft.)
25	50
20	75
15	125
10	175
Flatter than 10	200

2. The maximum drainage area for overland flow to a silt fence shall not exceed 1/2 acre per 100 feet of fence; and
3. Erosion would occur in the form of sheet erosion; and
4. There is no concentration of water flowing to the barrier; and
5. Where effectiveness is required for more than one construction season or 6 months, whichever is less.
6. As protection for a storm drain inlet refer to practice standard [INLET PROTECTION - FABRIC DROP 860](#).
7. As protection for a culvert inlet refer to practice standard [CULVERT INLET PROTECTION 808](#).

CRITERIA

All silt fences shall be placed as close to the contour as possible, with the ends extending upslope. The area below the fence must be undisturbed or stabilized.

Silt fence fabric shall meet the requirements in material specification [592 GEOTEXTILE](#) Table 1 or 2, Class I with an minimum apparent opening size (AOS) of 30 for non-woven and 50 for woven.

Fence posts shall be a minimum of 48 inches long. Wood posts shall be of sound quality wood with a minimum cross sectional area of 3.0 square inches. Steel posts shall be standard T and U sections weighing not less than 1.33 pound per linear foot or other steel posts having equivalent strength and bending resistance. The maximum spacing shall be 5 feet. When wire or other form of approved backing is used, the maximum spacing may be increased to 8 feet. The posts shall be driven a minimum of 18 inches into the ground or as approved by the engineer. Spacing may need to be adjusted so that posts are located in low areas where water may pond.

Wire fence shall be a minimum 12-gauge wire with a maximum 6-inch mesh opening. All other forms of support, such as polymeric mesh, shall be approved by the engineer/inspector.

The filter fabric shall be furnished in a continuous roll cut to the length of the silt fence needed to avoid splices. When splices are necessary, the fabric shall be spliced at a support post with a minimum 6-inch overlap, folded over and securely fastened so that silt-laden water cannot escape through the fence.

The height of a silt fence shall be a minimum of 24 inches above the original ground surface and shall not exceed a height of 30 inches above the ground surface. Wire or another form of approved support mesh backing shall be used on silt fences exceeding 24 inches in height.

The silt fence shall be entrenched to a minimum depth of 6 inches, with an additional 6 inches extending along the bottom of the trench in the upslope direction. When wire or another form of support mesh backing is used, the wire or other approved support mesh shall extend into the trench a minimum of 3 inches. The trench shall be backfilled and the soil compacted over the fabric.

The filter fabric and wire support, if used, must be securely fastened to the upslope side of the posts using heavy duty wire staples at least one inch long or tie wires (10 gage minimum), or in accordance with manufacturer's recommendations. The fabric shall not be stapled or wired to the wire support or to existing trees.

If the silt fence must cross contours, with the exception of the ends of the fence, gravel check dams placed perpendicular to the back of the fence shall be used to minimize concentrated flow and erosion along the back of the fence. The gravel check dams shall be approximately 1 foot deep at the back of the fence and be continued perpendicular to the fence at the same elevation until the top of the check dam intercepts the ground surface behind the fence. The gravel check dams shall consist of appropriately sized and specified rock for the fence line grade and contributing drainage area. The gravel check dams shall be located

every 10 feet along the fence where the fence must cross contours. The fence line grade and slope length in combination shall be stable after the installation of the check dams.

Silt fences shall be used prior to the establishment of erosion controls and installed prior to the clearing of existing vegetation.

CONSIDERATIONS

Silt fences should be considered for trapping sediment where sheet and rill erosion may be expected to occur in small drainage areas. Silt fences should not be placed in areas of concentrated flows.

Research has shown that silt fences can trap a much higher percentage of suspended sediments than can straw bale barriers and in most cases is the preferred option. As with straw bale barriers, improper placement as well as improper installation and maintenance of silt fences have, in many instances, significantly decreased the effectiveness of this practice.

While both woven and non-woven fabrics are commercially available, the woven fabric generally displays higher strength than the non-woven fabrics do. When tested under acid and alkaline water conditions, most of the woven fabrics increase in strength. There are a variety of reactions among non-woven fabrics. The same is true of testing under extensive ultra violet radiation. Permeability rates demonstrate very high filtering efficiencies for sandy sediments, there is considerable variation among both woven and non-woven fabrics when filtering the finer silt and clay particles.

PLANS AND SPECIFICATIONS

Plans and specifications for installing silt fences shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following:

1. Location where the silt fence is to be installed.
2. The type, size, and spacing of fence posts.
3. The type and size of wire or other approved support mesh backing, if used.
4. The type of filter fabric used.
5. The method of anchoring the filter fabric.
6. The method of fastening the filter fabric to the fencing support.
7. The rock size and location of gravel check dams, if used.

All plans shall include the installation, inspection, and maintenance schedules with the responsible party identified.

Standard Drawing [IL-620 SILT FENCE PLAN](#) or [IL-620W SILT FENCE WITH WIRE SUPPORT PLAN](#) can be used as the plan sheets.

OPERATION AND MAINTENANCE

Silt fences shall be removed when they have served their usefulness, but not before the upslope areas have been permanently stabilized.

Silt fences shall be inspected immediately after each rainfall and at least daily during prolonged rainfall.

Should the fabric decompose or become ineffective prior to the end of the expected usable life and the fence still is

necessary, the fabric or the entire system shall be replaced promptly.

Sediment deposits should be removed after each rainfall. They must be removed when the level of deposition reaches approximately one-half the height of the silt fence.

Any sediment deposits remaining in place after the silt fence is no longer required shall be dressed to conform to the existing grade, a seedbed prepared and the site vegetated.

ILLINOIS URBAN MANUAL
PRACTICE STANDARD

SODDING

(sq. ft.)
CODE 925

(Source: NC Erosion and Sediment Control Planning and Design Manual)

DEFINITION

Stabilization of fine-graded disturbed areas by laying a continuous cover of grass sod.

PURPOSE

The purposes of this practice are to prevent erosion and damage from sediment by stabilizing the soil surface and to improve the visual quality and utility of the area quickly.

CONDITIONS WHERE PRACTICE APPLIES

Disturbed areas, which require immediate cover for erosion protection or sediment control.

Where sodding is preferred to other means of grass establishment.

Residential or commercial areas where quick use or aesthetics are factors.

At places where surface water concentrates such as waterways carrying intermittent flows.

Areas around drop inlets or in swales.

Any area where conditions make seeding impractical or impossible.

CRITERIA

Final grade - Prior to soil preparation, areas to be sodded shall be brought to final grade in accordance with the approved plan. Any irregularities in soil surface shall be filled or shaped to prevent the formation of depressions or water pockets.

Soil Preparation - Soil tests should be made to determine the exact requirements for lime and fertilizer. Apply soil amendments uniformly and incorporate into the top 3 to 6 inches of the soil by disking or other acceptable means. Level with a harrow or similar tool. Roll lightly to firm surface after leveling. Prior to laying sod, the soil surface shall be clear of trash, debris, large roots, branches, stones, and clods in excess of 1 inch in length or diameter. Sod shall not be applied to gravel or other non-soil surface.

Sod - High quality sod free of disease, insects or weeds and consisting of about a 3/4 inch mat of vigorous turf will be selected. It shall not be cut or laid in excessively wet or dry weather. Sod shall be harvested, delivered, and installed within a period of 48 hours. The type of sod used must be composed of plants adapted to the site and suited for the use.

Sod Installation - Sod should not be laid if temperatures are too hot or too cold. The soil should be slightly moist but firm enough not to leave depressions if walked on. The first row shall be laid in a straight line perpendicular to the slopes with subsequent rows placed parallel to and butted tightly against each other. Lateral joints shall be staggered to promote more uniform growth and strength. Care shall be taken to prevent voids or over exposure of the roots which would cause drying. As sodding of defined areas is completed, sod shall be rolled or tamped to provide firm contact between roots and soil. Fill any gaps between edges or ends of sod mats with good soil and roll.

Watering - After rolling is complete, sod shall be irrigated to a depth sufficient that the underside of the sod mat and 4 inches of soil below sod is thoroughly wet. Irrigate at a rate that does not result in runoff. Until a good root system develops, supplement rainfall as often as necessary to maintain moist soil to a depth of at least 4 inches.

Mowing - Do not mow for 2-3 weeks or until at least 3 inches of new growth occurs. During the first 4 months do not remove more than 1/3 of the grass leaf at any one cutting.

CONSIDERATIONS

It is initially more costly to install sod than to seed. However, this cost is easily justified in places where sod can perform better than seed or where instant cover for erosion control or aesthetics is wanted.

Sod can be laid during times of the year when seeded grass may fail, so long as there is adequate water available for irrigation in the early weeks if establishment. Sod should not be laid during periods when the ground is frozen or during hot, dry periods.

Select high quality sod that is densely matted, healthy, weed-free and uniformly cut. Sod selected should always be freshly cut and laid within 48 hours. If sodding is delayed keep it cool and moist. High activity or critical runoff areas should be considered for sodding. Areas such as building entrance zones or where concentrated water flows occur should be sodded. Sod provides instant soil stabilization and acts as a natural filter of runoff.

On slopes greater than four (4) percent or where concentrated flows are likely the sod should be staked to prevent movement.

Select a sod that will meet the needs of the site. It will look good and will protect the site for years if properly selected and maintained.

PLANS AND SPECIFICATIONS

The plans for sodding shall specify the following:

1. Site preparation.
2. Fertilization.
3. Installation techniques.

4. Sod type, quality and quantity.
5. Watering.
6. Use and maintenance.

OPERATION AND MAINTENANCE

One of the main features of sod is that it permits almost immediate use of the area. Try to limit foot traffic to low use for the first 2 to 3 weeks. After that normal to high traffic levels can occur if normal growing conditions prevail.

Water the sod regularly, every week to 2 weeks, until a good root system develops. Moisten the soil uniformly to a depth of about 4 inches.

If the site was properly limed and fertilized prior to sodding only maintenance levels of nitrogen (N) phosphorus (P₂O₅) and potassium (K₂O) need to be applied.

Apply maintenance fertilizer beginning one year after sodding to maintain sod health, appearance and vigor. Amount and formulation of the fertilizer depends on the grass mixture and level of turf management. Turf management professionals should be consulted for specific recommendations. If no information is available, a total annual rate of 130 pounds of N per acre (3 pounds per 1,000 sq. ft.) and 40 pounds each of P₂O₅ and K₂O per acre (1 pound per 1,000 sq. ft.) should be applied. Apply as split applications, once in the spring after grass begins to grow (April-May) and once in the fall about 6 weeks before dormancy (August-September).

Mowing should occur as needed to maintain about 2 1/2 - 3 1/2 inches of grass. Generally, no more than 1/3 of

the total foliage should be removed during mowing.

Proper mowing height, fertilization and watering help maintain a disease and weed free sod. If weeds or diseases become a problem consult a turf specialist for treatment recommendations and adhere to label rates.

Special treatment, such as thatching aerating or rolling may be needed on an irregular basis. Consult a turf specialist for these issues.

Do not use sodium chloride salts on walks, or drives where runoff might damage the sod. Areas requiring resodding should be prepared in the same manner as the original installation.

NRCS IL December 1994

urbst925.doc

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

STABILIZED CONSTRUCTION ENTRANCE

(no.)
CODE 930

(Source: USDA – Natural Resources Conservation Service – Illinois)

DEFINITION

A stabilized pad of aggregate underlain with filter fabric located at any point where traffic will be entering or leaving a construction site to or from a public right-of-way, street, alley, sidewalk, or parking area.

PURPOSE

The purpose of this standard is to reduce or eliminate the tracking of sediment onto public right-of-ways or streets.

CONDITIONS WHERE PRACTICE APPLIES

A stabilized construction entrance shall be used at all points of construction ingress and egress.

CRITERIA

Stabilized construction entrance shall meet the following requirements:

Aggregate size - IDOT coarse aggregate gradations: CA-1, CA-2, CA-3, or CA-4.

Thickness - 6 inches or more.

Stone placement - The stone entrance for the entrance shall be placed according to construction specification [25 ROCKFILL](#). Placement will be by Method 1 and compaction will be class III.

Width - 14 feet minimum but not less than the full width of ingress or egress points.

Length - As required, but not less than 70 feet, except on a single residence lot where a 30 feet minimum shall apply.

Filter fabric shall be used under the aggregate to minimize the migration of stone into the underlying soil by heavy vehicle loads. The filter fabric shall meet the requirements of materials specification [592 GEOTEXTILE](#) Table 1 or 2, Class I, II, or IV.

All surface water flowing or diverted toward construction entrances shall be piped across the entrance. If piping is impractical, a mountable berm with 5:1 slopes will be permitted.

Washing - If conditions on the site are such that the vehicles traveling over the gravel do not remove the majority of the mud, then the tires of the vehicles must be washed before entering a public road. Wash water must be carried away from the entrance to a sediment trapping facility such as practice standards [IMPOUNDMENT STRUCTURE-ROUTED 842](#) or [TEMPORARY SEDIMENT TRAP 960](#). All sediment shall be prevented from entering storm drains, ditches, watercourses, or surface waters including wetlands. A wash rack may be used to make washing more convenient and effective.

Location - the washing station should be located to provide for maximum utility by all construction vehicles.

Timing - the graveled access shall be installed as soon as practical after the start of site disturbance.

Removal - the entrance shall remain in place and be maintained until the disturbed area is stabilized by permanent best management practices.

CONSIDERATIONS

Improperly planned and maintained construction entrances can become a continual erosion problem.

The tracking of mud from active building sites onto paved roads by construction vehicles can be greatly reduced, and in some cases eliminated, by the use of a

stabilized construction entrance. These entrances provide an area where mud can be removed from construction vehicle tires before they enter a public road.

If the action of the vehicle tires traveling over the stone is not sufficient to remove the majority of the mud, then the tires must be washed before the vehicle enters a public road. When washing is required it shall be done on an area stabilized with aggregate, or using a wash rack underlain with gravel. Provisions shall be made to intercept the wash water and trap the sediment before it is carried off-site. Construction entrances should be used in conjunction with the stabilization of construction roads, and other exposed areas, to reduce the amount of mud picked up by construction vehicles.

PLANS AND SPECIFICATIONS

Plans and specifications for installing stabilized construction entrances shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

1. Location.
2. Length.
3. Width.
4. Thickness.
5. Type of materials.

All plans shall include the installation, inspection, and maintenance schedules with the responsible party identified.

Standard drawing [STABILIZED CONSTRUCTION ENTRANCE PLAN IL-630](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

The entrance shall be maintained in a condition that will prevent tracking of sediment onto public right-of-ways or streets. This may require periodic top dressing with additional aggregate. All sediment spilled, dropped, or washed onto public right-of-ways must be removed immediately. Periodic inspection and needed maintenance shall be provided after each rain.

NRCS IL August 1994

urbst930.doc

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

STRAW BALE BARRIER

(ft.)
CODE 935

(Source: USDA - Natural Resources Conservation Service - Illinois)

DEFINITION

A temporary barrier consisting of a row of entrenched and anchored straw bales or similar material used to intercept sediment-laden runoff from small drainage areas of disturbed soil.

PURPOSE

The purpose of this practice is to cause deposition of transported sediment load from sheet flow leaving disturbed areas.

CONDITIONS WHERE PRACTICE APPLIES

A straw bale barrier may be used subject to the following conditions:

1. The maximum allowable slope lengths contributing runoff to a straw bale barrier are listed in the following table:

Slope (%)	Maximum Spacing (ft.)
25	25
20	50
15	75
10	100
Flatter than 10	125

2. The maximum drainage area for overland flow to a straw bale barrier shall not exceed 1/4 acre per 100 feet of barrier; and
3. Erosion would occur in the form of sheet and rill erosion; and
4. There is no concentration of water flowing to the barrier; and
5. Where effectiveness is required for less than 3 months.

CRITERIA

Straw bale barriers do not require any formal design but the following requirements must be met:

Bales shall be placed in a single row, lengthwise on the contour, with the ends of adjacent bales tightly abutting one another. The end bales should extend

upslope so that the trapped sediment laden water cannot flow around the ends of the barrier.

All bales shall be either wire-bound or string tied. Straw bales shall be installed so that bindings are oriented around the sides rather than along the tops and bottoms of the bales in order to prevent deterioration of the bindings. Hay or other baled material may be used in lieu of straw.

The barrier shall be entrenched and backfilled. A trench shall be excavated the width of a bale and the length of the proposed barrier to a minimum depth of 4 inches. After bales are staked and chinked, the excavated soil shall be backfilled and compacted against the barrier. Backfill soil shall conform to the ground level on the downhill side and shall be built up to 4 inches against the uphill side of the barrier.

Each bale shall be securely anchored by at least two stakes (minimum cross sectional area of 3.0 square inches or standard "T" or "U" steel posts (minimum weight of 1.0 pound per linear foot) or rebars driven through the bale. The first stake in each bale shall be driven toward the previously laid bale to force the bales together. Stakes or steel pickets shall be driven a minimum 18-inch deep into the ground to securely anchor the bales.

The holes between bales shall be chinked (filled by wedging) with straw to prevent water from escaping between the bales. Loose straw scattered over the area immediately uphill from a straw bale barrier tends to increase efficiency.

Straw bale barriers shall be installed prior to the clearing of existing vegetation or any site grading.

CONSIDERATIONS

Straw bale barriers should be considered for trapping sediment where sheet and rill erosion is occurring in small drainage areas. Straw bale barriers should not be placed in areas of concentrated flow. The practice standard [SILT FENCE 920](#) does the same job and is usually faster and cheaper to install.

Based on field observations in Illinois and other states, straw barriers have not been as effective as a sediment control measure as they could be. There are four major reasons for this. First, improper use of straw bales has been a major problem. Straw bale barriers have been used in streams and drainageways where high water velocities and/or volumes have destroyed them or significantly impaired their effectiveness. Second, improper placement and installation of the barriers, such as staking the bales directly to the ground with no soil seal or entrenchment has allowed undercutting and flow around the end. This has resulted in additions of, rather than removal of, sediment from runoff waters. Third, inadequate inspection and maintenance lowers the effectiveness of these barriers. Fourth, because straw bales decompose in the presence of moisture, they have a very limited life span.

PLANS AND SPECIFICATIONS

Plans and specifications for installing straw bale barriers shall be in keeping with this standard and shall describe the

requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

NRCS IL February 1994

urbst935.doc

1. The depth of trench required to bed the bales.
2. The method(s) required to anchor the bales.
3. The installation, inspection and maintenance schedules with the responsible party clearly identified.
4. The replacement schedule for bales.

Standard drawing [IL-635 STRAW BALE BARRIER PLAN](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

Straw bale barriers shall be inspected immediately after each runoff event and at least daily during prolonged rainfall. Close attention shall be paid to the repair of damaged bales, end runs and undercutting beneath bales. Necessary repairs to the barrier or replacement of bales shall be accomplished promptly.

Sediment deposits should be removed after each rainfall. They must be removed when the level of deposition reaches approximately one-half the height of the barrier.

Any sediment deposits remaining in place after the straw bale barrier is no longer required shall be dressed to conform to the existing grade, prepared and seeded.

Straw bale barriers shall be removed when they have served their usefulness, but not before the upslope areas have been permanently stabilized.

STRUCTURAL STREAMBANK STABILIZATION

(ft.)
CODE 940

(Source: McHenry County Soil and Water Conservation District)

DEFINITION

Stabilization of eroding streambanks by use of designed structural measures.

PURPOSE

The purpose of this practice is to protect streambanks from the erosive forces of flowing water.

CONDITIONS WHERE PRACTICE APPLIES

Sections of streambanks that are subject to erosion due to excessive runoff from construction activities. Generally applicable where flow velocities exceed 5 ft/sec or where vegetative streambank protection is inappropriate.

CRITERIA

Since each reach of channel requiring protection is unique, measures for structural streambank protection should be installed according to a plan based on specific site conditions.

Develop designs according to the following principles:

1. Make protective measures compatible with other channel modifications planned or being carried out in other channel reaches.
2. Use the minimum design velocity of the peak discharge of the 10-year storm. Structural measures must be effective for this design flow and must be capable of withstanding greater flows without serious damage.
3. Ensure that the channel bottom is stable or stabilized by structural means before installing any permanent bank protection.
4. Ensure that streambank protection extends between stabilized or controlled points along the stream.
5. Do not change channel alignment without a complete evaluation of the anticipated effect on the rest of the stream channel, especially downstream.
6. Give special attention to maintaining and improving habitat for fish and wildlife.
7. Ensure that all requirements of state law and all permit requirements of

local, state, and federal agencies are met.

Riprap - Riprap is the most commonly used structural material for stabilizing streambanks. When possible, slope banks to 2:1 or flatter, and place a gravel filter or filter fabric on the smoothed slopes before installing riprap. Place the toe of the riprap at least 1 foot below the stream channel bottom or below the anticipated depth of channel degradation. Where necessary, riprap the entire length between well-stabilized points of the stream channel.

Riprap shall be installed according to the requirements in construction specification [61 LOOSE ROCK RIPRAP](#).

Gabions - These rectangular, rock-filled wire baskets are pervious, semi-flexible building blocks that can be used to armor the bed and/or banks of channels or act as deflectors to divert flow away from eroding channel sections. Gabions shall be installed according to the requirements in construction specification [64 WIRE MESH GABIONS](#).

Reinforced concrete - May be used to armor eroding sections of the streambank by constructing retaining walls or bulkheads. Provide positive drainage behind these structures. Reinforced concrete may also be used as a channel lining for stream stabilization.

Grid pavers - Modular concrete units with interspersed void areas that can be used to armor the streambank while maintaining porosity and allowing the establishment of vegetation. These structures may be obtained in precast

blocks or mats that come in a variety of shapes, or they may be formed and poured in place. Keep design and installation in accordance with manufacturer's instructions.

Revetment - Structural support or armoring to protect an embankment from erosion. Riprap or gabions are commonly used. Gabions may be either stacked or placed as a mattress. Install revetment to a depth below the anticipated channel degradation and into the channel bed as necessary to provide stability. Stabilize all areas disturbed by construction as soon as the structural measures are complete.

CONSIDERATIONS

Stream channel erosion problems vary widely in type and scale, and there is no one measure that works in all cases. Stabilization structures should be planned and designed by an engineer with experience in this field. Many of the practices discussed here involve the use of manufactured products and should be installed in accordance with the manufacturer's specifications. Where long reaches of stream channels require stabilization, make detailed stream studies.

Before selecting a structural stabilization technique, the designer should carefully evaluate the possibility of using vegetative stabilization in conjunction with structural measures to achieve the desired protection. Vegetative techniques are generally less costly and more compatible with natural stream characteristics.

PLANS AND SPECIFICATIONS

A detail of the streambank stabilization shall be shown on the plan, and contain the following minimum requirements.

1. Location and extent of streambank to be stabilized.
2. A detail of the protective layer.
3. Thickness and gradation of riprap, if used.
4. Specifications for the materials used including the filter or filter fabric.

Standard drawing [IL-640 STRUCTURAL STREAMBANK STABILIZATION PLAN](#) may be used as the plan sheet for riprap and standard drawings [IL-641](#), [IL-642](#), [IL-643](#), [IL-644](#), OR [IL-645 STRUCTURAL STREAMBANK STABILIZATION - GABIONS](#) may be used as the plan sheet for gabions.

OPERATION AND MAINTENANCE

Check stabilized streambank sections after every high water event, and make any needed repairs immediately to prevent further damage.

NRCS IL August 1994

urbst940.doc

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

SUBSURFACE DRAIN

(ft.)
CODE 945

(Source: USDA Natural Resources Conservation Service - Illinois)

DEFINITION

A conduit, such as corrugated plastic tubing, tile, or pipe, installed beneath the ground surface to collect and/or convey drainage water.

PURPOSE

The purposes of this practice are to:

1. Improve the soil environment for vegetative growth, reduce erosion, and improve water quality by:
 - a. Regulating the water table and ground water flows,
 - b. Intercepting and preventing water movement into a wet area,
 - c. Relieving artesian pressures,
 - d. Removing surface runoff,
 - e. Leaching of saline and sodic soils,
 - f. Serving as an outlet for other subsurface drains, and
 - g. Regulating subirrigated areas or waste disposal areas.
2. Collect ground water for beneficial uses.
3. Remove water from heavy use areas, such as around buildings,

roads, and play areas; and accomplish other physical improvements related to water removal.

4. Regulate water to control health hazards caused by pests such as liver fluke, flies, or mosquitoes.

CONDITIONS WHERE PRACTICE APPLIES

This practice applies to areas having a high water table where the benefits of lowering the water table or controlling ground water or surface runoff justify installing such a system.

This standard applies to areas suitable for the intended use after installation of required drainage and other conservation practices. The soil shall have enough depth and permeability to permit installation of an effective and economically feasible system. The ability to drain and treat saline and sodic soils shall be considered where this is a problem.

In areas where an outlet is available, either by gravity flow or by pumping, the

outlet shall be adequate for the quantity and quality of effluent to be discharged.

CRITERIA

The design and installation shall be based on adequate surveys and investigations.

Capacity - The required capacity shall be determined by one or more of the following:

1. Application of a locally tried and proven drainage coefficient to the acreage drained, including added capacity required to dispose of surface water entering through inlets.
2. Yield of ground water based on the expected deep percolation of irrigation water from the overlying fields, including the leaching requirement.
3. Comparison of the site with other similar sites where subsurface drain yields have been measured.
4. Measurement of the rate of subsurface flow at the site during a period of adverse weather and ground water conditions.
5. Application of Darcy's law to lateral or artesian subsurface flow.
6. Estimates of lateral or artesian subsurface flow.

The minimum required drainage coefficient shall be determined from the Illinois Drainage Guide, for the kinds of crop grown and degree of existing drainage.

Size - The size of subsurface drains shall be computed by applying Manning's formula. The size shall be based on the required capacity and

computed by using one of the following assumptions:

1. The hydraulic gradeline is parallel to the bottom grade of the subsurface drain with the conduit flowing full at design flow.
2. The conduit flowing partly full where a steep grade or other conditions require excess capacity.
3. Conduit flowing under pressure with hydraulic gradeline set by site conditions on a grade that differs from that of the subsurface drain. This procedure shall be used only if surface water inlets or nearness of the conduit to outlets with fixed water evaluations permit satisfactory estimates of hydraulic pressure and flows under design conditions.

All subsurface drains shall have nominal diameter that equals or exceeds 3 inches.

Depth, spacing, and location - The depth, spacing, and location of the subsurface drain shall be based on site conditions, including soils, topography, ground water conditions, crops, land use, outlets, and saline or sodic conditions.

The minimum depth of cover over subsurface drains in mineral soils shall be 2 ft. This minimum depth shall apply to normal field levels and may exclude sections of line near the outlet or sections laid through minor depressions where the conduit is not subject to damage by frost action or equipment travel.

The minimum depth of cover in organic soils shall be 2.5 ft. for normal field levels, as defined above, after initial subsidence. Structural measures shall

be installed if it is feasible to control the water table level in organic soils within the optimum range of depths.

The maximum depth of cover for standard duty corrugated plastic tubing shall be 10 ft for trench widths of 2 ft or less. Heavy-duty tubing shall be specified for depths greater than 10 ft, trench widths more than 2 ft, or in rocky soils. For computation of maximum allowable loads on subsurface drains, use the trench and bedding conditions specified and the crushing strength of the kind and class of drain. The design load on the conduit shall be based on a combination of equipment loads and trench loads. Equipment loads are based on the maximum expected wheel loads for equipment to be used, the minimum height of cover over the conduit, and the trench width. Equipment loads on the conduit may be negated when the depth of cover exceeds 6 ft. Trench loads are based on the type of backfill over the conduit, the width of the trench, and the unit weight of the backfill material. A safety factor of not less than 1.5 shall be use in computing the maximum allowable depth of cover for a particular type of conduit.

Minimum velocity and grade - In areas where sedimentation is not a hazard, the minimum grades shall be based on site conditions and a velocity not less than 0.5 ft/sec. If a sedimentation hazard exists, a velocity of not less than 1.4 ft/sec shall be used to establish the minimum grades. Otherwise, provisions shall be made for preventing sedimentation by use of filters or by collecting and periodically removing sediment from installed traps, or by periodically cleaning the lines with high-

pressure jetting systems or cleaning solutions.

Maximum velocity without protection. Excessive flow velocity in the drain may induce piping of soil material into the drain line.

TABLE 1
Maximum Velocities by Soil Texture

Soil Texture	Velocity (ft./sec.)
Sand & sandy loam	3.5
Silt & silt loam	5.0
Silty clay loam	6.0
Clay & clay loam	7.0
Coarse sand or gravel	9.0

Maximum grade and protection - On sites where topographic conditions require that drain lines be placed on steep grades and design velocities will be greater than indicated under "Maximum velocity without protection," special measures shall be used to protect the conduit or surrounding soil. These measures shall be specified for each job according to the particular conditions of the site.

The protective measures shall include one or more of the following:

1. Enclose continuous perforated pipe or tubing with fabric-type filter material or properly graded sand and gravel.
2. Use nonperforated continuous tubing, a watertight pipe, or seal joints.
3. Place the conduit in a sand and gravel envelope or blinding with the least erodible soil available.
4. Select rigid butt end pipe or tile with straight smooth sections and square ends to obtain tight fitting joints.

5. Wrap open joints of the pipe or tile with tar-impregnated paper, burlap, or special fabric-type filter material.
6. Install open-air risers for air release or entry.

Iron ochre considerations - If drains are to be installed in sites where iron ochre problems are likely to occur, provisions should be made to provide access for cleaning the lines. Each drain line should outlet directly into an open ditch and/or should have entry ports as needed to provide access for cleaning equipment. Drain cleaning provisions should be installed in such a way that the drains can be cleaned in an upstream or rising grade direction. If possible, drains in ochre-prone areas should be installed during the dry season when the water table is low and the iron is in its insoluble form.

Where possible, in areas where the potential for ochre problems is high, protection against ochre development can be provided by designing an outlet facility to ensure permanent submergence of the drain line.

Protection against root clogging -

Problems may occur where it is necessary to place drains in close proximity to perennial vegetation. Roots of water-loving trees, such as willow, cottonwood, elm, and soft maple, or some shrubs and grasses growing near subsurface drains may enter and obstruct the flow.

The first consideration is to use nonperforated tubing or closed joints through the root zone area. Where this is not possible, water-loving trees should be removed from a distance of at least 100-ft on each side of the drain. A distance of 50 ft should be maintained from other species of trees except for

fruit trees. Orchards can often be drained by drains located close to the fruit trees.

Where crops and grasses may cause trouble to drain lines, facilities may be installed to provide a means for submerging the line to terminate the root growth as desired or to maintain a water table above the drainlines to prevent growth into the system.

Materials - Subsurface drains include conduits of plastic, clay, concrete, bituminized fiber, metal, or other materials of acceptable quality. The conduit shall meet strength and durability requirements of the site.

Foundation - If soft or yielding foundations are encountered, the lines shall be stabilized and protected from settlement by adding gravel or other suitable materials to the trench, by placing the conduit on a treated plank that will not readily decompose or on other rigid supports, or by using long sections of non-perforated watertight pipe having adequate strength to insure satisfactory subsurface drain performance. The use of a flat treated plank is not recommended for corrugated plastic tubing.

Filters and Filter Material - Filters will be used around conduits, as needed, to prevent movement of the surrounding soil material into the conduit. The need for a filter will be determined by the characteristic of the surrounding soil material, site conditions, and velocity of flow in the conduit. A suitable filter should be specified if:

1. Local experience indicates a need,
2. Soil materials surrounding the conduit are dispersed clays, low

plasticity silts, or fine sands (ML or SM with P.I less than 7),

3. Where deep soil cracking is expected, or
4. Where the method of installation may result in voids between the conduit and backfill material.

If a sand-gravel filter is specified, the filter gradation will be based on the gradation of the base material surrounding the conduit within the following limits:

D15 size smaller than 7 times d85 size but not smaller than 0.6 mm.

D15 size larger than 4 times d15 size, less than 5% passing No. 200 sieve, maximum size smaller than 1.5 inches.

D represents the filter material and d represents the surrounding base material. The number following each letter is the percent of the sample, by weight that is finer than that size. For example, D15 size means that 15 percent of the filter material is finer than that size.

Specified filter material must completely encase the conduit so that all openings are covered with at least 3 inches of filter material except that the top of the conduit and side filter material may be covered by a sheet of plastic or similar impervious material to reduce the quantity of filter material required. Artificial fabric or mat-type filter materials may be used, provided that the effective opening size, strength, durability, and permeability are adequate to prevent soil movement into the drain throughout the expected life of the system.

Envelopes and envelope material - Envelopes shall be used around

subsurface drains if they are needed for proper bedding of the conduit or to improve the characteristics of flow of ground water into the conduit.

Materials used for envelopes do not need to meet the gradation requirements of filters, but they must not contain materials that will cause an accumulation of sediment in the conduit or that will render the envelope unsuitable for bedding of the conduit.

Envelope materials shall consist of sand-gravel, organic, or similar material. Sand-gravel envelope materials shall all pass a 1.5 inch sieve; not more than 30 percent shall pass a No. 60 sieve; and not more than 5 percent shall pass the No. 200 sieve. ASTM-C-33 fine aggregate for concrete has been satisfactorily used and is readily available.

Where organic or other compressible materials are used, they shall be used only around a rigid wall conduit and above the centerline or flexible tubing. All organic or other compressible material shall be of a type that will not readily decompose.

Placement and bedding - The conduit should not be placed on exposed rock or stones more than 1.5 inches in diameter. Where such conditions are present the trench must be overexcavated a minimum of 6 inches and refilled to grade with a suitable bedding material.

The conduit must be placed on a firm foundation to insure proper alignment. If installation will be below a water table or where unstable soils are present, special equipment, installation procedures, or bedding materials may

be needed. These special requirements may also be necessary to prevent soil movement into the drain or plugging of the envelope if installation will be made in such materials as quicksand or a silt slurry. For trench installations of corrugated plastic tubing 8 inches or less in diameter, one of the following bedding methods will be specified:

1. A shaped groove or 90 degree V-notch in the bottom of the trench for tubing support and alignment.
2. As sand-gravel envelope, at least 3 inches thick, to provide support.
3. Compacted soil bedding material beside and to 3 inches above the tubing.

For trench installations of corrugated plastic tubing larger than 8 inches, the same bedding requirements will be met except that a semi-circular or trapezoidal groove shaped to fit the conduit will be used rather than a V-shaped groove.

For rigid conduits installed in a trench, the same requirements will be met except that a groove or notch is not required.

All trench installations should be made when the soil profile is in its driest possible condition in order to minimize problems of trench stability, conduit alignment, and soil movement into the drain.

For trench installations where a sand-gravel or compacted bedding is not specified, the conduit should be blinded with selected material containing no hard objects larger than 1.5 inches in diameter. Blinder should be carried to a minimum of 3 inches above the conduit.

Auxiliary structures and protection -

Structures installed in drain lines must not unduly impede the flow of water in the system. Their capacity must be no less than that of the line or lines feeding into or through them. The use of internal couplers for corrugated plastic tubing will be allowed.

If the drain system is to carry surface water flow, the capacity of the surface water inlet shall not be greater than the maximum design flow in the drain line or lines. Covers, orifice plates, and/or trash racks should be used to ensure that no foreign materials are allowed in the drain lines.

The capacity of a relief well system will be based on the flow from the aquifer, the well spacing, and other site conditions and will be adequate to lower the artesian waterhead to the desired level.

The size of relief wells is generally based on the available material rather than on hydraulic consideration. Such wells will not be less than 4 inches in diameter.

Junction boxes, manholes, catch basins, and sand traps must be accessible for maintenance. A clear opening of not less than 2 feet will be provided in either circular or rectangular structures. The drain system must be protected against velocities exceeding those proved under "Maximum velocity without protection" and against turbulence created near outlets, surface inlets, or similar structures. Continuous or closed joint pipe must be used in drain lines adjoining the structure where excessive velocities will occur.

Junction boxes shall be installed where three or more lines join or if two lines join at different elevations. In some locations it may be desirable to bury junction boxes. A solid cover should be used, and the junction box should have a minimum of 1 1/2 foot of soil cover.

If not connected to a structure, the open end of each subsurface drain line will be capped with a tight-fitting cap of the same material as the conduit or other durable materials.

The outlet must be protected against erosion and undermining of the conduit, entry of tree roots, damaging periods of submergence, and entry of rodents or other animals into the subsurface drain. A continuous section of rigid pipe without open joints or perforations will be used at the outlet end of the line and must discharge above the normal elevation of low flow in the outlet ditch. Corrugated plastic tubing is not suitable for the outlet section. Minimize the visual impact of projecting outlets.

Continuously submerged outlets will be permitted for water table control systems.

The outlet pipe and its installation will conform to the following requirements:

1. If burning vegetation on the outlet ditch bank is likely to create a fire hazard; the material from which the outlet pipe is fabricated must be fire resistant. If the likelihood is great, the outlet pipe must be fireproof.
2. Two-thirds of the pipe will be buried in the ditch bank, and the cantilever section must extend to the toe of the ditch side slope or the side protected from erosion. The minimum length of the pipe will normally be 8 feet.

Under certain conditions shorter sections are appropriate, e.g., steep-sided main and laterals (1:1 or less) with a narrow bottom width of 3 feet, commonly referred to as "minimum ditches," for outletting individual subsurface drain laterals. For conduits 10 inches in diameter and greater, longer outlet sections should be considered, such as:

10 inches and 12 inches in diameter, use 12 feet.

15 inches and 18 inches in diameter, use 16 feet.

Use 20-foot outlet pipe for all diameters larger than 18 inches.

3. If ice or floating debris may damage the outlet pipe, the outlet shall be recessed to the extent that the cantilevered part of the pipe will be protected from the current in the ditch.
4. Headwalls used for subsurface drain outlets must be adequate in strength and design to avoid washouts and other failures.

Watertight conduits strong enough to withstand the expected loads will be used if subsurface drains cross under irrigation canals, ditches, or other structures. Conduits under roadways must be designed to withstand the expected loads. Shallow subsurface drains through depressed or low areas and near outlets must be protected from damage caused by farm machinery and other equipment and from freezing and thawing.

CONSIDERATIONS

Consideration shall be given to possible damages above or below the point of discharge that might involve legal

actions under state or local laws. Consideration shall be given to maintaining or enhancing environmental values.

Septic tanks and other waste disposal systems shall not be connected to subsurface drain systems.

Where wetlands will be affected, the cooperators will be advised and USDA-NRCS wetland policy shall apply.

PLANS AND SPECIFICATIONS

Plans and specification for installing subsurface drains shall be in keeping with this standard and include the following:

1. Drain location and alignment.
2. Drain depth and grade.
3. Filter and envelope requirements (if used).
4. Material requirements.
5. Backfilling requirements.

OPERATION AND MAINTENANCE

A properly designed and installed subsurface drain requires little maintenance. However, check drains periodically and especially after heavy rains to see that they are operating properly. Keep the outlet free of sediment and other debris, and keep the animal guard in place and functional. Investigate any wet areas along the line for possible cave-in due to vehicle traffic, blockage by roots, or other problems. Make all needed repairs promptly.

urbst945.doc

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

SUMP PIT

(no.)

CODE 950

(Source: USDA – Natural Resources Conservation Service – Illinois)

DEFINITION

A temporary pit which is constructed to trap and filter water for pumping into a suitable discharge area.

PURPOSE

The purpose of this practice is to remove excessive water from excavations in a manner that improves the quality of the water being pumped.

CONDITIONS WHERE PRACTICE APPLIES

Sump pits are constructed when water collects during the excavation phase of construction. This practice is particularly useful in urban areas during excavation for building foundations.

CRITERIA

A perforated vertical standpipe is placed in the center of the pit to collect filtered water. The standpipe will be a perforated 12 to 24-inch diameter corrugated metal or PVC pipe. Water is then pumped from the center of the pipe

to a suitable discharge area. The pit will be filled with coarse aggregate meeting the requirements of IDOT standards for gradations of CA-2, CA-3 or CA-4.

CONSIDERATIONS

Discharge of water pumped from the standpipe should be to a suitable practice such as practice standard [IMPOUNDMENT STRUCTURE-ROUTED 842](#), [PORTABLE SEDIMENT TANK 895](#), [TEMPORARY SEDIMENT TRAP 960](#), or a stabilized area. If water from the sump pit will be pumped directly to a storm drainage system, filter fabric will be wrapped around the standpipe to ensure clean water discharge. The fabric, if used, shall meet the requirements as shown in material specification [592 GEOTEXTILE](#) Table 1 or 2, Class 1 with an equivalent opening size of at least 30 for non-woven or 50 for woven. It is recommended that 1/4 to 1/2 inch hardware cloth wire be wrapped around and secured to the standpipe prior to attaching the filter fabric. This will increase the rate of water seepage into the standpipe.

PLANS AND SPECIFICATIONS

Plans and specifications for installing and utilizing sump pits shall be in keeping with standard and shall describe the requirements for applying the practice to achieve its intended purpose.

The contractor or responsible reviewing authority will determine the number of sump pits and their locations.

Standard drawing [IL-650 SUMP PIT PLAN](#) may be used as a plan sheet.

All plans shall include the installation, inspection, and maintenance schedules with the responsible party identified.

OPERATION AND MAINTENANCE

The sump pit may have to be replaced if the pit and filter fabric plugs with sediment.

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

SURFACE ROUGHENING

(acre or sq. ft.)
CODE 953

(Source:VA Erosion and Sediment Control Handbook)

DEFINITION

A rough soil surface with horizontal grooves running across the slope on the contour, stair stepping, or tracking with construction equipment.

PURPOSE

The purposes of this practice are to aid in the establishment of vegetative cover from seed, reduce runoff velocity, increase infiltration, reduce erosion, and provide for sediment trapping.

CONDITIONS WHERE PRACTICE APPLIES

Areas that have been graded and are to be stabilized with vegetation established by seed without use of an erosion control mat.

Areas that have been graded and will not be permanently stabilized immediately.

Slopes with a stable rock face do not require roughening or stabilization.

CRITERIA

All slopes steeper than 3:1 (horizontal to vertical) shall be surface roughened by either stair-step grading, grooving, or tracking.

Areas with slopes flatter than 3:1 shall have the soil surface lightly roughened and loosened to a depth of 2 to 4 inches prior to seeding.

Stair-step grading shall consist of cutting a slope into stair steps. Each step shall have a vertical cut depth to horizontal step length of less than 1:1. The horizontal portion of the step shall slope toward the vertical wall. Individual vertical cuts shall not be more than 30 inches on soft materials and not more than 40 inches in rocky materials.

Grooving shall consist of using machinery to create a series of ridges and depressions that run perpendicular to the slope (on the contour). Grooves shall not be less than 3 inches deep nor further than 15 inches apart except for areas that will be mowed where the

grooves shall not be less than 1 inch deep nor further than 10 inches apart.

Tracking shall consist of surface roughening with tracked machinery. Tracking shall only be used on coarse texture or relatively dry, finer-texture soils to avoid compaction of the soil. The tracked machinery shall be operated up and down the slope to leave horizontal depressions in the soil. Back-blading shall not be permitted during the final grading operation. The number of machinery passes shall be limited to minimize soil compaction.

All surface roughened areas shall be seeded and mulched as soon as possible to obtain optimum seed germination and seedling growth. Seeding and mulching shall be completed in accordance with practice standards [MULCHING 875](#), [PERMANENT VEGETATION 880](#), or [TEMPORARY SEEDING 965](#), as appropriate.

Fill slopes that are surface roughened by allowing the surface to remain rough as the fill is placed and compacted shall have a loose uncompacted surface depth of 4 to 6 inches.

CONSIDERATIONS

Rough slope surfaces are preferred because they aid in the establishment of vegetation, improve water filtration, and decrease runoff velocity. Graded areas with smooth, hard surfaces may be initially attractive, but such surfaces increase the potential for erosion. A rough, loose soil surface gives a mulching effect that protects lime, fertilizer and seed. Nicks in the surface are cooler and provide more favorable

moisture conditions than hard, smooth surfaces; this aids seed germination.

There are different methods for achieving a roughened soil surface on a slope, and the selection of an appropriate method depends upon the type of slope. Factors to be considered in choosing a method are slope steepness, mowing requirements, and whether the slope is formed by cutting or filling.

Stair-step grading may be carried out on any material soft enough to be ripped with a bulldozer. Slopes consisting of soft rock with some subsoil are particularly suited to stair-step grading.

Grooves may be made with any appropriate implement that can be safely operated on the slope and which will not cause significant compaction. Suggested implements include offset discs, tillers, spring harrows, chisel rippers, and the teeth on a front-end loader bucket.

For areas that will be mowed, surface roughening should consist of shallow grooves created by normal tilling, disking, harrowing, or use of a cultipacker-seeder. The final pass of any such implement shall be on the contour.

Tracking is generally not as effective as the other roughening methods described since the soil surface is more likely to be compacted which results in less infiltration of runoff.

PLANS AND SPECIFICATIONS

Plans and specifications for surface roughening shall be in keeping with this standard and shall describe the

requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

1. Location
2. Method and equipment needed

All plans shall include installation, inspection, and maintenance schedules with the responsible party identified.

OPERATION AND MAINTENANCE

The slope shall be inspected after every runoff producing rain and repairs made as needed. Fill any eroded areas to slightly above the original grade, re-roughen the surface, then re-seed and mulch as soon as possible.

TEMPORARY DIVERSION

(ft.)
CODE 955

(Source: NC Erosion and Sediment Control Planning and Design Manual)

DEFINITION

A temporary ridge or excavated channel or combination ridge and channel constructed across sloping land on a predetermined grade.

PURPOSE

The purpose of this practice is to protect work areas from upslope runoff and to divert sediment-laden water to an appropriate sediment trapping facility or stabilized outlet.

CONDITIONS WHERE PRACTICE APPLIES

This practice applies to construction areas where runoff can be diverted and disposed of properly to control erosion, sedimentation, or flood damage. Specific locations and conditions include:

1. Above disturbed existing slopes, and above cut or fill slopes to prevent runoff over the slope;
2. Across unprotected slopes, as slope breaks, to reduce slope length;

3. Below slopes to divert excess runoff to stabilized outlets;
4. Where needed to divert sediment-laden water to sediment traps such as practice standard [IMPOUNDMENT STRUCTURE-ROUTED 842](#);
5. At or near the perimeter of the construction area to keep sediment from leaving the site;
6. Above disturbed areas before stabilization to prevent erosion and maintain acceptable working conditions.
7. Temporary diversions may also serve as sediment traps when the site has been overexcavated on a flat grade. They may also be used in conjunction with a silt fence, practice standard [SILT FENCE 920](#).
8. Where active construction activities make the use of a permanent practice standard [DIVERSION 815](#) unfeasible.

CRITERIA

Temporary diversions must be planned to be stable throughout their useful life and to meet the criteria given below.

Those not meeting the criteria stated below will be designed as permanent diversions. See practice standard DIVERSION 815.

1. Drainage area will not exceed three acres.
2. The minimum cross section will be as follows:

Top Width (ft.)	Height (ft.)	Side Slopes
0	1.5	4:1
4	1.5	2:1

3. The grade may be variable depending upon the topography and must have a positive grade to the outlet. The maximum channel grade will be limited to 1.0 percent.
4. The maximum spacing of diversions on side slopes or graded rights-of-way will be no greater than the following:

Land Slope (%)	Maximum Spacing (ft.)
1 or less	300
2 – 3	200
3 – 5	150
5 or greater	100

5. Diverted runoff will outlet onto a stabilized area, into a properly designed waterway, grade stabilization structure or sediment trapping facility.
6. Diversions that are to serve longer than 30 working days shall be seeded and mulched meeting the requirements in practice standards [TEMPORARY SEEDING 965](#) and [MULCHING 875](#) as soon as they are constructed to preserve dike height and reduce maintenance.

7. The channel cross section may be parabolic, v-shaped or trapezoidal.

CONSIDERATIONS

It is important that diversions are properly designed, constructed and maintained since they concentrate water flow and increase erosion potential. Particular care must be taken in planning diversion grades. Too much slope can result in erosion in the diversion channel or at the outlet. A change of slope from steeper grade to flatter may cause deposition to occur. The deposition reduces carrying capacity and may cause overtopping and failure.

Frequent inspection and timely maintenance are essential to the proper functioning of diversions. Sufficient area must be available to construct and properly maintain diversions.

It is usually less costly to excavate a channel and form a ridge or dike on the downhill side with the spoil than to build diversions by other methods. Where space is limited, it may be necessary to build the ridge by hauling in diking material or using a silt fence to divert the flow. Use gravel to armor the diversion dike where vehicles must cross frequently.

Temporary diversions may serve as in-place sediment traps if overexcavated 1 to 2 feet and placed on a nearly flat grade. The dike serves to divert water as the stage increases. A combination silt fence and channel in which fill from the channel is used to stabilize the fence can trap sediment and divert runoff simultaneously.

Wherever feasible, build and stabilize diversions and outlets before initiating other land-disturbing activities. Construction of diversions will be in compliance with Illinois drainage laws.

PLANS AND SPECIFICATIONS

Plans and specifications for installing temporary diversions shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

1. Diversion location.
2. Channel grade.
3. Diversion cross-sections.
4. Seeding and fertility rates.

All plans shall include the installation, inspection, and maintenance schedules with the responsible party identified.

Construction of the diversion shall meet the requirements as listed in the construction specification [27 DIVERSIONS AND WATERWAYS](#); standard drawing [IL-655 TEMPORARY DIVERSION PLAN](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

Inspect temporary diversions once a week and after every rainfall. Immediately remove sediment from the flow area and repair the diversion ridge. Carefully check outlets and make timely repairs as needed. When the area protected is permanently stabilized, remove the ridge and the channel to blend with the natural ground level and appropriately stabilize it.

NRCS IL August 1994

urbst955.doc

TEMPORARY SEDIMENT TRAP

(no.)
CODE 960

(Source: NC Erosion and Sediment Control Planning and Design Manual)

DEFINITION

A small, temporary ponding basin formed by construction of an embankment or excavated basin.

PURPOSE

The purpose of this practice is to detain sediment-laden runoff from small-disturbed areas for a sufficient period of time to allow the majority of sediment and other water-based debris to settle out.

CONDITIONS WHERE PRACTICE APPLIES

1. At the outlets of diversions, channels, slope drains, or other runoff conveyances that discharge sediment-laden water.
2. Below areas that are 5 acres or less.
3. Where access can be maintained for sediment removal and proper disposal.
4. In the approach to a storm water inlet located below a disturbed area as part of an inlet protection system.

5. Structure life should be limited to 18 months.
6. Where failure of the structure will not result in loss of life, damage to homes, commercial or industrial buildings, main highways or railroads; or in the use or service of public utilities.

CRITERIA

Storage capacity - Designs shall provide for both sediment storage and detention storage.

The sediment storage shall be sized to store the estimated sediment load generated from the site over the duration of the construction period with a minimum storage equivalent to the volume of sediment generated in one year. For construction periods exceeding one year, the one-year sediment load and a sediment removal schedule may be substituted.

The detention storage shall be composed of equal volumes of "wet" and "dry" detention storage. Each shall be sized for the runoff from either a 2-

year, 24-hour storm from the area draining into the basin under maximum runoff conditions during construction, or 134 cubic yards/acre based on the area draining into the basin, whichever is greater. Half of the detention storage shall be below the permeable fill.

Embankment - Ensure that embankments for temporary sediment traps do not exceed 5 feet in height measured at the centerline from the original ground surface to the top of the embankment. Additional freeboard may be added to the embankment height to allow flow through a designed bypass location. Construct embankments with a minimum top width of 5 feet and side slopes of 2:1 or flatter. Machine compact embankments according to the requirements in construction specification [23 EARTHFILL](#).

The design height of the embankment shall be increased by the amount needed to insure that after settlement the height of the dam equals or exceeds the design height. The height of the embankment shall be increased by 5% where the fill material is placed in lifts of 8" or less and compacted by heavy equipment traversing the fill. The height shall be increased by 10% when fill material is pushed up and compacted by a bulldozer.

The original ground under the embankment shall be scarified to a depth of 6" or more prior to placement of the fill material. Fill material shall not be placed over frozen ground. The earthen embankment shall be seeded with temporary or permanent vegetation in accordance with methods outlined in the practice standards [PERMANENT VEGETATION 880](#) or [TEMPORARY SEEDING 965](#).

Excavation - Where sediment pools are formed or enlarged by excavation, keep side slopes at 2:1 or flatter for safety.

Outlet section - Construct the sediment trap outlet using a stone section of embankment located at the low point in the basin. The stone section serves two purposes: 1) the top section serves as a nonerosive spillway outlet for flood flow, and 2) the bottom section provides a means of dewatering the basin between runoff events.

Stone size - A combination of coarse aggregate and riprap shall be used to provide for filtering/detention as well as outlet stability. Construct the outlet using well-graded stones with a d50 size of 9 inches and a maximum stone size of 14 inches (IDOT RR-4). A 1-foot thick layer of 1/2-inch rock (IDOT CA-2) should be placed on the inside face to reduce drainage flow rate.

Side slopes stone layer thickness - Keep the side slopes of the spillway at least 21 inches thick.

Depth - Keep the crest of the spillway outlet a minimum of 1.5 feet below the settled top of the embankment.

Protection from piping - Place filter cloth, according to the requirements in material specification [592 GEOTEXTILE](#) Table 1 or 2, Class I, II or IV with an AOS of 30 for nonwoven and 50 for woven, between the soil and the riprap to prevent piping. An alternative would be to excavate a keyway trench across the riprap foundation and up the sides to the height of the dam.

Weir length and depth - Keep the spillway weir at least 4 feet long and sized to pass the peak discharge of the 10 year frequency, 24-hour duration

storm without failure, overtopping of the basin or significant erosion. A maximum flow depth of 1 foot, a minimum freeboard of 0.5 feet, and maximum side slopes of 2:1 are required. Weir length may be selected from the table below:

Drainage Area (acres)	Weir Length (ft.)
1	4.0
2	6.0
3	8.0
4	10.0
5	12.0

Dimensions shown are minimum.

The release rate of the basin shall be that rate required to achieve minimum detention times of at least 10 hours. The elevation of the permeable fill outlet shall be placed such that it only drains the dry detention storage.

Direct spillway bypass to natural, stable areas. Locate bypass outlets so that flow will not damage the embankment.

Discharges from both the principal and emergency spillways of a sediment trap must be conveyed to a natural waterway in a channel of adequate capacity and stability. Where this channel intersects with the natural waterway, the discharge shall be less than 1 1/2 feet per second or otherwise below the velocity which will initiate erosion or scour within the receiving waterway. Outlets to stormwater facilities must have adequate capacity to receive the discharge from the sediment trap.

Where an emergency spillway is utilized, the spillway crest elevation should be at least 1.5 feet below the settled top of the embankment with the emergency spillway crest being 0.5 feet below the top of the embankment.

Rock placement - The rock will be placed according to construction specification [25 ROCKFILL](#). Placement will be by Method 1 and compaction of rockfill will be Class III.

CONSIDERATIONS

Select locations for sediment traps during site evaluation. Note natural drainage divides and select trap sites so that runoff from potential sediment-producing areas can easily be diverted into the traps.

Make traps readily accessible for periodic sediment removal and other necessary maintenance. Plan locations for sediment disposal as part of trap site selection. Clearly designate all disposal areas on the plans.

In preparing plans for sediment traps, it is important to consider provisions to protect the embankment from failure from storm runoff that exceeds the design capacity. Consider nonerosive emergency spillway bypass areas, particularly if there could be severe consequences from failure. If a bypass is not possible and failure would have severe consequences, consider alternative sites.

Sediment trapping is achieved primarily by settling within a permanent pool formed by excavation, or by a combination of excavation and embankment. Sediment-trapping efficiency is a function of surface area and inflow rate. Installations that provide pools with large length to width ratios reduce short-circuiting and allow more of the pool surface area for settling. This optimizes efficiency.

The minimum length of flow through the trap should be 10 feet and the minimum

length to width ratio should be 2:1. If site conditions permit a greater travel distance through the basin and greater length to width ratio the water quality benefit provided by the sediment trap will be enhanced. The average trap permanent pool depth should be a minimum of 3 feet to prevent resuspension of sediments.

Another method of improving the trapping efficiency is to place geotextile fabric between the riprap and coarse aggregate. If this is done, timely maintenance is needed to assure that the outlet does not clog with sediment.

Because well-planned sediment traps are key measures to preventing off-site sedimentation, they should be installed in the first stages of project development.

PLANS AND SPECIFICATIONS

Plans and specifications for temporary sediment traps shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

1. Location of the sediment traps.
2. Size of basin including width, length and depth.
3. Minimum cross section of embankment.
4. Minimum profile through spillway.
5. Location of emergency spillway, if used.
6. Gradation and quality of rock.

All plans shall include the installation, inspection, and maintenance schedules with the responsible party identified.

The standard drawing [IL-660 TEMPORARY SEDIMENT TRAP](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

Inspect temporary sediment traps after each period of significant rainfall. Remove sediment and restore the trap to its original dimensions when the sediment has accumulated to one-half the design depth of the permanent pool. Place the sediment that is removed in the designated disposal area and replace the contaminated part of the gravel facing.

Check the structure for damage from erosion or piping. Periodically check the depth of the spillway to ensure it is a minimum of 1.5 feet below the low point of the embankment to slightly above design grade. Any riprap displaced from the spillway must be replaced immediately.

After all sediment-producing areas have been permanently stabilized, remove the structure and all unstable sediment. Smooth the area to blend with the adjoining areas and stabilize properly.

TEMPORARY SEEDING

(acre or sq. ft.)

CODE 965

(Source: USDA Natural Resources Conservation Service - Illinois)

DEFINITION

Planting rapid-growing annual grasses or small grains, to provide initial, temporary cover for erosion control on disturbed areas.

PURPOSE

The purpose of this practice is to temporarily stabilize denuded areas that will not be brought to final grade or on which construction will be stopped for a period of more than 14 working days.

Temporary seeding helps reduce runoff and erosion until permanent vegetation or other erosion control measures can be established. In addition, it provides residue for soil protection during seedbed preparation and reduces problems of mud and dust production from bare soil surfaces during construction.

CONDITIONS WHERE PRACTICE APPLIES

This practice applies to all cleared, unvegetated, or sparsely vegetated soil

surfaces where vegetative cover is needed for less than 1 year.

Applications of this practice include diversions, dams, temporary sediment basins, temporary road banks, topsoil stockpiles and any other exposed areas of a construction site.

CRITERIA

Plant selection - Select plants appropriate to the season and site conditions from Table 1.

Site preparation - Prior to seeding, install necessary erosion control and sediment control practices if possible.

Remove large rocks or other debris that may interfere with seedbed preparation or seeding operations.

Seedbed preparation:

1. Liming: Where the pH of the soil is below 5.5, apply one and one half to two tons per acre of finely ground agricultural limestone. If the seeding period is less than 30 days liming will not be required.

2. Fertilizer: Apply 500 pounds per acre of 10-10-10 fertilizer or equivalent. Incorporate lime and fertilizer into the top 2 - 4 inches of soil. If the seeding period is less than 30 days fertilizer will not be required.
3. Prepare a seedbed of loose soil to a depth of 3 to 4 inches. If recent tillage or grading operations have resulted in a loose surface, additional tillage or roughening may not be required except to break up large clods. If rainfall caused the surface to become sealed or crusted, loosen it just prior to seeding by disking, raking, harrowing, or other suitable methods. Groove or furrow slopes steeper than 3:1 on the contour before seeding.

Seeding - Seed shall be evenly applied with a cyclone seeder, drill, cultipacker seeder or hydroseeder. Small grains shall be planted no more than one inch deep. Grasses shall be planted no more than one half inch deep.

Cover broadcast seedings by cultipacking, dragging a harrow, or raking.

Mulching - Seedings made during optimum spring and summer seeding dates, with favorable soil and site conditions, will not require mulch.

When temporary protection is needed see practice standard MULCHING 875.

CONSIDERATIONS

Temporary seedings should be used to protect earthen structures such as dikes, diversions, dams and other structures used for sediment control during construction. Temporary seedings can also reduce the amount of

maintenance these structures may need. For example, the frequency of sediment basin clean-outs will be reduced if watershed areas, outside the active construction zone, are stabilized.

Proper seedbed preparation, selection of appropriate species, and use of quality seed are as important in this practice as in practice standard [PERMANENT VEGETATION 880](#).

Failure to follow established guidelines and recommendations carefully might result in an inadequate or short-lived stand of vegetation that will not control erosion.

Temporary seeding provides protection for no more than 1 year, during which time permanent stabilization should be initiated.

PLANS AND SPECIFICATIONS

Plans and specifications for temporary seeding shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

1. Plant species to be used
2. Dates of seeding
3. Seedbed preparation
4. Fertilization and seeding rates and methods.

All plans shall include the installation, inspection, and maintenance schedules with the responsible party identified.

OPERATION AND MAINTENANCE

Reseed areas where seedling emergence is poor, or where erosion occurs, as soon as possible. Protect from vehicular and foot traffic. Control weeds by mowing.

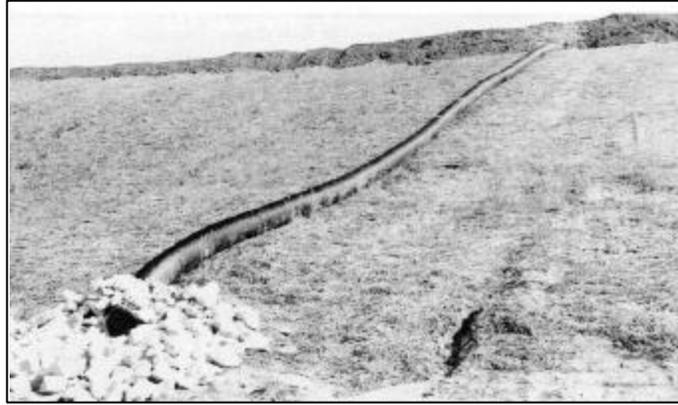

TABLE 1

TEMPORARY SEEDING SPECIES, RATES AND DATES

Species	Lbs./Acre	Lbs./1000 ft. ²	Seeding Dates
Oats	90	2	Early spring – July 1
Cereal Rye	90	2	Early spring – Sept. 30
Wheat	90	2	Early spring – Sept. 30
Perennial Ryegrass	25	0.6	Early spring – Sept. 30

TEMPORARY SLOPE DRAIN

(no.)
CODE 970

(Source: IN Handbook for Erosion Control on Developing Areas)

DEFINITION

A flexible tubing or rigid conduit extending temporarily from the top to the bottom of a cut or fill slope.

PURPOSE

The purpose of this practice is to convey concentrated runoff down the face of a cut or fill slope without causing erosion on or below the slope.

CONDITIONS WHERE PRACTICE APPLIES

This practice applies to construction areas where stormwater runoff above a cut or fill slope will cause erosion if allowed to flow over the slope. Temporary slope drains are generally used in conjunction with temporary diversions or diversion dikes to convey runoff down a slope until permanent water disposal measures can be installed. The maximum allowable drainage area is 5 acres per slope drain.

CRITERIA

Capacity - Peak runoff from the 10-year frequency, 24-hour duration storm.

Dike design - An earthen dike, meeting the requirements of practice standards [TEMPORARY DIVERSION 955](#) or [DIVERSION DIKE 820](#), shall be used to direct stormwater runoff into the temporary slope drain.

Pipe size - Unless individually designed, size drains according to the following table:

Pipe/Tubing Diameter (D)	Maximum Drainage Area
12 inches	0.5 acres
18 inches	1.5 acres
21 inches	2.5 acres
24 inches	3.5 acres
30 inches	5.0 acres

Inlet - The height of the earth dike at the entrance to the pipe slope drain shall be equal to or greater than the diameter of the pipe, $D + 18$ inches and at least 6 inches higher than the adjoining ridge on either side. The lowest point of the

ridge should be a minimum of 1 foot above the top of the drain so that design flow can freely enter the pipe. The minimum top width of the dike at the inlet shall be 4 feet. The inlet may be a standard IDOT flared end section with a minimum 6-inch toe plate. A standard T-section fitting may also be used. All connections shall be watertight. Appropriate inlet protection shall be used if a sediment trapping facility is impractical downstream. If ponding will cause a problem at the inlet and make such protection impractical, appropriate sediment removing measures shall be taken at the outlet of the pipe.

Outlet - The pipe slope drain shall outlet into a sediment-trapping device when the drainage area is disturbed. A riprap apron meeting the requirements of practice standard [ROCK OUTLET PROTECTION 910](#) shall be installed below the pipe outlet where water is being discharged into a stabilized area.

Conduit - The conduit shall have a slope of 3 percent or steeper and be installed with watertight connecting bands. The conduit material may be smooth iron; corrugated metal or heavy duty non-perforated corrugated plastic pipe or specially designed flexible tubing.

Install reinforced, hold-down grommets or stakes to anchor the conduit at intervals not to exceed 10 ft with the outlet end securely fastened in place. The conduit must extend beyond the toe of the slope. Terminate the drain in a 4-foot level section where practical.

CONSIDERATIONS

There is often a significant lag between the time a cut or fill is graded and the time it is permanently stabilized. During

this period, the slope is very vulnerable to erosion, and temporary slope drains together with temporary diversions can provide valuable protection.

Temporary slope drains must be sized, installed, and maintained properly, because failure will usually result in severe erosion of the slope. The entrance section to the drain should be well entrenched and stable so that surface water can enter freely. The drain should extend downslope beyond the toe of the slope to a stable area or outlet.

Other points of concern are failure from overtopping from inadequate pipe inlet capacity or blockage and lack of maintenance of diversion channel capacity and ridge height.

PLANS AND SPECIFICATIONS

Plans and specifications for installing temporary slope drains shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

1. Drain location.
2. Inlet type.
3. Conduit size and material.
4. Conduit hold down device.
5. Ridge height over conduit.

All plans shall include the installation, inspection, and maintenance schedules with the responsible party identified.

Standard drawing [IL-670 TEMPORARY SLOPE DRAIN PLAN](#) may be used as a plan sheet.

OPERATION AND MAINTENANCE

Inspect the slope drain and supporting diversion once a week and after every rainfall and promptly make necessary repairs. The contractor should avoid the placement of any material on and prevent construction traffic across the slope drain. When the protected area has been permanently stabilized, temporary measures may be removed, materials disposed of properly, and all disturbed areas stabilized appropriately.

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

TEMPORARY STREAM CROSSING

(no.)
CODE 975

(Source: Kane-DuPage Soil and Water Conservation District)

DEFINITION

A bridge, ford, or temporary structure installed across a stream or watercourse for short-term use by construction vehicles or heavy equipment.

PURPOSE

The purpose of this practice is to provide a means for construction vehicles to cross streams or watercourses without moving sediment into streams, damaging the streambed or channel, or causing flooding.

CONDITIONS WHERE PRACTICE APPLIES

Where heavy equipment must be moved from one side of a stream channel to another, or where light-duty construction vehicles must cross the stream channel frequently for a short period of time. Generally, a temporary stream crossing is applicable to flowing streams with drainage areas less than 1 square mile. More exacting engineering methods should be used on larger drainage areas.

CRITERIA

In addition to erosion and sediment control, structural stability, utility, and safety must also be taken into consideration when designing temporary stream crossings. Bridge designs in particular, should be completed by a qualified engineer.

The anticipated life of a temporary stream crossing structure is usually considered to be 1 year or less. Remove the structure immediately after it is no longer needed.

As a minimum, design the structure to pass bank full flow or peak flow, whichever is less, from a 2-year frequency, 24-hour duration storm without over topping. Ensure that no erosion will result from the 10-year peak storm.

Ensure that design flow velocity at the outlet of the crossing structure is non-erosive for the receiving stream channel.

Consider overflow for storms larger than the design storm and provide a protected overflow area.

A water diverting structure such as a swale shall be constructed (across the roadway on both roadway approaches) 50 feet maximum on either side of the waterway crossing. This will prevent roadway surface runoff from directly entering the waterway. The 50 feet is measured from the top of the waterway bank. If the roadway approach is constructed with a reverse grade away from the waterway, a separate diverting structure is not required.

The aggregate for the roadway shall be a minimum of 6 inches thick stone or recycled concrete meeting one of the following IDOT coarse aggregate gradations: CA-1, CA-2, CA-3 or CA-4.

The aggregate will be placed on geotextile fabric meeting the requirements in material specification [592 GEOTEXTILE](#) Table 1 or 2, class I, II, or IV.

CONSIDERATIONS

Careful planning can minimize the need for stream crossings. Try to avoid crossing streams, whenever possible, complete the development separately on each side and leave a natural buffer zone along the stream. Temporary stream crossings are a direct source of water pollution; they may create flooding and safety hazards; they can be expensive to construct; and they cause costly construction delays if washed out.

Select locations for stream crossings where erosion potential is low. Evaluate stream channel conditions, overflow areas, and surface runoff control at the

site before choosing the type of crossing. When practical, locate and design temporary stream crossings to serve as permanent crossings to keep stream disturbance to a minimum.

Plan stream crossings in advance of need, and when possible, construct them during dry periods to minimize stream disturbance and reduce cost. Ensure that all necessary materials and equipment are on-site before any work is begun. Complete construction in an expedient manner and stabilize the area immediately.

When construction requires dewatering of the site, construct a bypass channel before undertaking other work. If stream velocity exceeds that allowed for the in-place soil material, stabilize the bypass channel with riprap or other suitable material. After the bypass is completed and stable, the stream may be diverted.

Unlike permanent stream crossings, temporary stream crossings may be allowed to overtop during peak storm periods. However, the structure and approaches should remain stable. Keep any fill needed in floodplains to a minimum to prevent upstream flooding and reduce erosion potential. Use riprap to protect locations subject to erosion from overflow.

Where appropriate, install in-stream sediment traps immediately below stream crossings to reduce downstream sedimentation. When used, excavate the basin a minimum of 2 feet below the stream bottom and approximately two times the cross-sectional flow area of the existing channel. Ensure that the flow velocity through the basin does not exceed the allowable flow velocity for

the in-place soil material; otherwise it should not be excavated. In locations where trees or other vegetation must be removed, the sediment trap may be more damaging to the stream than if it was not installed.

Stream crossings are of three general types: bridges, culverts and fords. Consider which method best suits the specific site conditions.

Bridges - Where available materials and designs are adequate to bear the expected loading, bridges are preferred for temporary stream crossing.

Bridges usually cause the least disturbance to the streambed, banks, and surrounding area. They provide the least obstruction to flow and fish migration. They generally require little or no maintenance, can be designed to fit most site conditions, and can be easily removed and materials salvaged. However, bridges are generally the most expensive to design and construct. Further, they may offer the greatest safety hazard if not adequately designed, installed, and maintained, and if washed out, they cause a longer construction delay and are more costly to repair.

In steep watersheds it is recommended to tie a cable or chain to one corner of the bridge frame with the other end secured to a large tree or other substantial object. This will prevent flood flows from carrying the bridge downstream where it may cause damage to property.

Culvert crossings - Culverts are the most common stream crossings. In many cases, they are the least costly to install, can safely support heavy loads,

and are adaptable to most site conditions. Construction materials are readily available and can be salvaged. However, the installation and removal of culverts causes considerable disturbance to the stream and surrounding area. Culverts also offer the greatest obstruction to flood flows and are subject, therefore, to blockage and washout.

Fords - Fords made of stabilizing material such as rock are often used in steep areas subject to flash flooding, where normal flow is shallow (less than 3 inches deep) or intermittent. Fords should only be used where crossings are infrequent. Fords are especially adapted for crossing wide, shallow watercourses.

When properly installed, fords offer little or no obstruction to flow, can safely handle heavy loading, are relatively easy to install and maintain, and, in most cases, may be left in place at the end of the construction.

Problems associated with fords include the following: 1) approach sections are subject to erosion. Generally do not use fords where bank height exceeds 5 feet, 2) excavation for the installation of the riprap-gravel bottom and filter material causes major stream disturbance. In some cases, fords may be adequately constructed by shallow filling without excavation, 3) the stabilizing material is subject to washing out during storm flows and may require replacement, 4) mud and other contaminants are brought directly into the stream on vehicles unless crossings are limited to no flow conditions.

PLANS AND SPECIFICATIONS

Plans and specifications for temporary stream crossing shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

1. The location of the crossing.
2. Required material specifications.

All plans shall include the installation, inspection, and maintenance schedules with the responsible party identified.

Standard drawing [IL-675 TEMPORARY STREAM CROSSING PLAN](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

Inspect temporary stream crossings after runoff-producing rains to check for blockage in channel, erosion of abutments, channel scour, riprap displacement, or piping. Make all repairs immediately to prevent further damage to the installation.

Remove temporary stream crossings immediately when they are no longer needed. Restore the stream channel to its original cross-section, and smooth and appropriately stabilize all disturbed areas.

Leave in-stream sediment traps in place to continue capturing sediment.

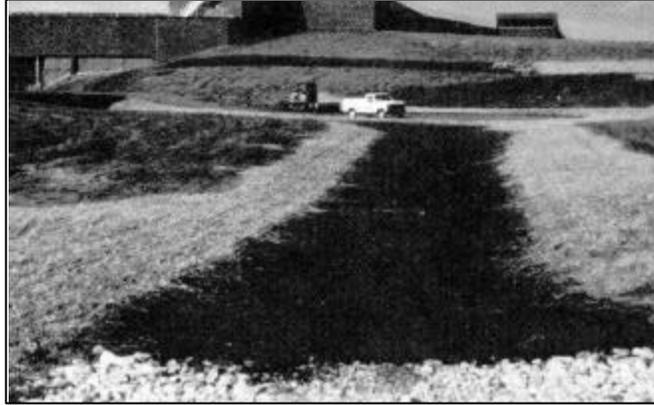

NRCS IL August 1994

urbst975.doc

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

TEMPORARY SWALE

(ft.)
CODE 980

(Source: MN Protecting Water Quality in Urban Areas)

DEFINITION

A temporary excavated drainageway.

PURPOSE

The purposes of this practice are to prevent runoff from entering disturbed areas by intercepting and diverting it to a stabilized outlet and to intercept sediment-laden water in disturbed areas and divert it to a sediment-trapping device.

CONDITIONS WHERE PRACTICE APPLIES

Temporary swales are constructed:

1. To divert flows from entering a disturbed area.
2. Intermediately across disturbed areas to shorten overland flow distances.
3. To direct sediment-laden water along the base of slopes to a sediment trapping device.
4. To transport off-site flows across disturbed areas such as rights-of-way.

This standard applies to swales draining 10 acres or less. For drainage areas larger than 10 acres, refer to the practice standard [GRASS-LINED CHANNEL 840](#).

CRITERIA

The channel cross section shall be designed using the criteria in Table 1.

Stabilization of the swale shall be completed within 10 days of installation in accordance with the practice standards [TEMPORARY SEEDING 965](#), [PERMANENT VEGETATION 880](#), [MULCHING 875](#), [EROSION BLANKET 830](#).

The flow channel shall be stabilized using the criteria in Table 2.

All stone or concrete linings will be placed on geotextile fabric meeting the requirements in material specification [592 GEOTEXTILE](#) Table 1 or 2, class I, II, or IV. In highly erodible soils refer to the next higher slope grade for type of stabilization. Recycled Concrete Equivalent shall be concrete broken to

the required size, and shall contain no steel reinforcement.

In areas where the drainage area is undisturbed, the swale shall have an outlet that functions without erosion, and dissipates runoff velocity prior to discharge off the site. Examples of stable outlets include [LEVEL SPREADER 870](#) and [ROCK OUTLET PROTECTION 910](#).

In areas where the drainage area is disturbed, runoff shall be conveyed to a sediment trapping facility until the drainage area above the swale is adequately stabilized. Examples of appropriate sediment trapping facilities include practice standards [IMPOUNDMENT STRUCTURE - ROUTED 842](#) or [TEMPORARY SEDIMENT TRAP 960](#).

CONSIDERATIONS

The on-site location may need to be adjusted to meet field conditions in order to utilize the most suitable outlet condition.

If the temporary swale is used to divert flows from entering a disturbed area, a sediment-trapping device may not be needed.

PLANS AND SPECIFICATIONS

Plans and specifications for installing temporary swales shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

1. Location where the practice is to be installed.
2. Cross-section and grade of channel.

3. Type of stabilization treatment and materials to be used.

All plans shall include the installation, inspection, and maintenance schedules with the responsible party identified.

Standard drawings [IL-680R TEMPORARY ROCK SWALE PLAN](#) or [IL-680V TEMPORARY VEGETATED SWALE PLAN](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

Vegetated swale channels should be inspected regularly to check for points of scour, bank failure or inadequate vegetative cover; rubbish or channel obstruction; rodent holes or excessive wear from pedestrian or construction traffic.

Swales collecting runoff from disturbed areas shall remain in place until the disturbed areas are permanently stabilized.

Lined swale channels should be checked regularly for deterioration from freezing, salt or chemicals; scour or undermining at the inlet and outlet; or points of sediment deposition.

Any needed repairs shall be made promptly.

NRCS IL February 1994

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

TOPSOILING

(acre or sq. ft.)
CODE 981

(Source: VA Erosion and Sediment Control Handbook)

DEFINITION

Methods of preserving and using topsoil to enhance final site stabilization with vegetation.

PURPOSE

The purpose of this practice is to provide a suitable growth medium for final site stabilization with vegetation.

CONDITIONS WHERE PRACTICE APPLIES

1. Where the preservation or importation of topsoil is determined to be the most effective method of providing a suitable growth medium.
2. Where the subsoil or existing soil present any or all of the following problems:
 - a. The texture, bulk density, pH, or nutrient balance of the available soil cannot be modified by a reasonable means to provide an adequate growth medium for the desired vegetation.
 - b. The soil is too shallow to provide adequate rooting depth or will not

supply necessary moisture and nutrients for growth of desired vegetation.

- c. The soil contains substances toxic or potentially toxic to the desired vegetation.
3. Where high-quality turf or ornamental plants are desired.

CRITERIA

Determine if sufficient quantities of suitable topsoil as described in material specification [804 MATERIAL FOR TOPSOILING](#) is available at the site or nearby. Topsoil shall be spread at a lightly compacted depth of 2 to 4 inches. Depths of 4 inches or greater are recommended where fine-textured (clayey) subsoil or other root limiting factors are present.

If topsoil is to be stockpiled at the site, select a location so that it will not erode, block drainage, or interfere with work on the site.

During construction of the project, soil stockpiles shall be stabilized or protected with sediment trapping

measures such as practice standards [SILT FENCE 920](#) or [TEMPORARY SEEDING 965](#). Perimeter controls shall be placed around the stockpile immediately; seeding of stockpiles shall be completed within 7 days of formation of the stockpile if it is to remain dormant for longer than 30 days.

Bonding - If the topsoil and existing soil surface are not properly bonded water will not infiltrate evenly, and it will be difficult to establish vegetation.

Care must be taken not to apply topsoil to an existing soil surface if the two have contrasting textures. Clayey topsoil over sandy subsoil is a particularly poor combination, as water creeps along the junction between the two soil layers and may cause the topsoil to slough.

Do not apply topsoil to slopes greater than 2:1 to avoid slippage. Topsoiling of steep slopes should be discouraged unless good bonding of the soils can be achieved.

Depending on subsoil conditions, additional measures may be required for ornamental shrub and tree plantings. See practice standard [TREE AND SHRUB PLANTING 985](#).

CONSIDERATIONS

Topsoil is the surface layer of the soil profile, generally characterized as darker than the subsoil due to the enrichment with organic matter. It is the major zone of root development and biological activity. Microorganisms that enhance plant growth thrive in this layer. Topsoil can usually be differentiated from subsoil by texture as well as color. Clay content usually increases in the subsoil. Where subsoils are high in

clay, the topsoil layer may be significantly coarser in texture. The depth of natural topsoil may be quite variable. On severely eroded sites it may be gone entirely.

Advantages of topsoil include its higher organic matter content, friable consistence (soil aggregates can be easily crushed with only moderate pressure), its available water holding capacity, and its nutrient content. Most often it is superior to subsoil in these characteristics. The texture and friability of topsoil are usually much more conducive to seedling germination, emergence, and root growth.

In addition to being a better growth medium, topsoil is often less erodible than subsoil, and the coarser texture of topsoil increases infiltration capacity and reduces runoff.

Although topsoil may provide an improved growth medium, there may be disadvantages, too. Stripping, stockpiling, hauling, and spreading topsoil or importing topsoil may not be cost-effective. Handling may be difficult if large amounts of branches or rocks are present or if the terrain is too rough. Most topsoil contains weed seeds, which compete with desirable species.

In site planning, compare the options of topsoiling with preparing a seedbed in the available subsoil. The clay content of many subsoils retains moisture. When properly limed and fertilized, subsoil may provide a satisfactory growth medium, which is generally free of weed seeds.

Topsoiling is normally recommended where ornamental plants or high-maintenance turf will be grown. It may

also be required to establish vegetation on shallow soils; soils containing potentially toxic materials, stony soils, and soils of critically low pH (highly acid).

NRCS IL February 1994

urbst981.doc

PLANS AND SPECIFICATIONS

The plans and specifications for installing topsoiling shall be in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose. At a minimum include the following items:

1. Topsoil source.
2. Stockpile location and method of stabilization prior to its use.
3. Topsoil/subsoil bonding procedures.
4. Site preparation plans and method of application, distribution and compaction.

All plans shall include the installation, inspection, and maintenance schedules with the responsible party identified.

The application of topsoil shall meet the requirements as listed in the construction specification [752 STRIPPING, STOCKPILING SITE PREPARATION AND SPREADING TOPSOIL](#).

OPERATION AND MAINTENANCE

After topsoil application, follow procedures for seedbed preparation. Take care to avoid excessive mixing of topsoil into the subsoil. Permanently stabilize the site following appropriate practice standards as quickly as practicable. Periodically inspect the site until permanent stabilization is achieved. Make necessary repairs to eroded areas or areas of light vegetative cover.

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

TREE AND FOREST ECOSYSTEM PRESERVATION

(acre or sq. ft.)
CODE 984

(Source: USDA - Natural Resources Conservation Service - Illinois)

DEFINITION

The preservation of contiguous stands of trees from damage during construction operations.

PURPOSE

The purpose of this practice is to preserve contiguous forested areas and stands of trees that have present and future value for erosion protection, wildlife habitat, landscape aesthetics, and other economic and environmental benefits.

CONDITIONS WHERE PRACTICE APPLIES

This practice applies on development sites containing stands of trees.

CRITERIA

The Critical Forest Edge Zone (CFEZ) is one foot outside the perimeter of the leaf canopy of the stand of trees to be protected. The area within the CFEZ

shall be protected from damage during construction operations.

All required protection measures shall be installed prior to the commencement of any site development activity and shall remain in place and in working, functional order until all site development activities have ceased or the surrounding area has been stabilized.

No construction activities shall be permitted within the CFEZ. In addition, all roadways, parking areas, and storage areas shall be located outside the CFEZ.

Construction fencing (florescent polyethylene laminar safety netting), wooden snow fence, or approved equivalent with a minimum height of 40 inches shall be installed around the CFEZ of all forested areas to be preserved, prior to pruning. The fencing shall be secured to ground-mounted metal or wood posts spaced a maximum of 6 feet apart and maintained to

prevent clearing, grading and development activities from encroaching within the CFEZ.

If a higher degree or more permanent protection is desired, a chain link fence following criteria in Construction Specification [91 CHAIN LINK FENCE](#), a wire fence following criteria in Construction Specification [92 FIELD FENCE](#), or a comparable wooden structure may be used.

Signs shall be posted which identify the enclosed areas as the CFEZ.

Appropriate soil erosion and sediment control measures shall be installed outside of the CFEZ to prevent sediment from reaching the CFEZ.

When utilities or other development features necessitate underground movement of the soil within the critical root zone, follow criteria in practice standard [TREE PROTECTION - AUGERING 991](#). There shall be no trenching within the critical root zone of any tree within the protected area of the CFEZ. The critical root zone is defined as being one foot outside the perimeter of the dripline or leaf canopy of an individual tree.

Measures must be installed according to a site-specific plan and in accordance with all applicable local, state, and federal laws and regulations.

CONSIDERATIONS

Preserving and protecting trees and other natural plant groups often result in more stable soil and aesthetically pleasing development.

When working within the boundary of a municipality, local authorities such as

the Urban Forester, City Arborist, Municipal Forester or Horticulturist, or Public Works officials should be contacted to determine locally enforced tree protection/preservation standards.

Tree surveys should be required for all parcels that contain mature woodlands, groves, young woodlands or significant trees. Tree surveys should identify the location, size (caliper), species, and condition health rating of all trees having a diameter at breast height (DBH) of 12 inches or more. Property line and hedgerow trees should be included in the tree survey. Required tree surveys and inventories should be conducted by a certified arborist or a professional forester.

It is recommended that a professional forester review the pre-construction plan; supervise/inspect the on-site tree protection operation; and review the site for compliance during the post-construction phase.

It is recommended that a professional forester, licensed landscape architect, or an agency designee with biological, natural resource or environmental credentials select the trees to be preserved before siting roads, buildings or other structures.

If trees are to be removed, it is recommended that a professional forester should be present to supervise the tree removals to make recommendations to ensure the dropped trees minimize damage to protected trees. All trees to be removed will be recorded by stem diameter so that responsible party can conduct natural area mitigation by planting enough trees to replace the trees on at least one for one replacement schedule.

Complete removal of all the trees on site followed by total site compaction well beyond the project perimeter is not recommended.

For sites greater than 15 acres in size that are unique examples of biodiversity as identified by authorized agencies/commissions, or where the area will be greatly impacted by the project and no other viable option exists, a natural resources team consisting of a forester, soil scientist, and botanist should be formed to determine the alternative that least damages the resource.

The following features should be considered when developing sites in and around wooded areas:

1. Rare and endangered species
2. Historical or archeological significance
3. Quantity and quality of forested area in the county or local governmental area
4. Frailty of resources without existing trees
5. Potential for soil erosion with the absence of the forest cover
6. The loss of aesthetic quality of the site; existence of critical areas (such as flood plains, steep slopes, and wet lands)
7. Unique flora and fauna
8. Health and condition of the individual trees and the forest ecosystem
9. Loss of habitat and flora and fauna species diversity
10. Groups of trees to be saved on the erosion control plan

A mitigation plan for damaged trees should be prepared in consultation with a professional forester or certified arborist and included with construction plans and contract documents.

PLANS AND SPECIFICATIONS

Plans and specifications for tree and forest ecosystem preservation shall be in keeping with this standard and will describe the requirements for applying the practice. At a minimum include the following items:

1. Forested areas to be preserved.
2. Location and type of fencing to be used to protect the trees.
3. Locations of construction areas, traffic patterns and roadways, storage areas and parking pads, and the construction project in relationship to the CFEZ to be preserved.
4. Types and locations of signs.

All plans shall include the installation, inspection and maintenance schedules with the responsible person clearly identified.

Standard drawing [IL-690 TREE PROTECTION - FENCING](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

On active construction sites protected areas should be inspected at least every 7 days for compliance and any repairs made as needed.

The protective signs and fences shall be removed only after all construction work has been finished, including final grading and shaping of the site, and the site has been inspected by a professional forester for damages to the trees.

Inspections shall include a listing of trees with damage to trunks, mounding of soil around the trunk, evidence of root

damage, and evidence of improper pruning.

and John Hartman. University of Kentucky Agricultural Communications.

TREE AND SHRUB PLANTING

(acre or sq. ft.)

CODE 985

(Source: National Arbor Day Foundation)

DEFINITION

Planting of selected trees and shrubs.

PURPOSE

The purpose of this standard is to establish trees and/or shrubs to conserve soil, beautify, screen unsightly views, provide shade and attract wildlife.

CONDITIONS WHERE PRACTICE APPLIES

In urban environments where woody tree and shrub species are needed to protect the soil from erosion, where ornamental plants are desirable for landscaping and beautification and where woody plants are needed to screen unsightly views, reduce noise levels or provide wildlife food and habitat.

CRITERIA

Select tree and shrub species suited to the soil and site conditions and adapted to the plant hardiness zone in which the planting site is located.

Keep the roots of bare root stock moist at all times prior to planting. The ball of balled and burlapped (B&B) stock and the soil of container grown stock shall be kept moist but not saturated prior to planting.

Plant trees and shrubs at a spacing that will provide enough space for full crown development. Ornamental and shade trees shall have a minimum spacing of 20 feet by 20 feet and ornamental shrubs at 5 feet by 5 feet. Trees and shrubs planted as noise barriers, screen plantings and windbreaks shall have a minimum spacing of 8 feet by 8 feet for trees and 4 feet by 8 feet for shrubs.

All bare root, container grown and balled and burlapped (B&B) planting stock shall meet the minimum root system spread criteria as established in construction specification [707-DIGGING, TRANSPORTING, PLANTING AND ESTABLISHMENT OF TREES, SHRUBS AND VINES](#).

All plant materials will be dormant at the time they are planted. Planting dates and procedures shall conform to those

established by construction specification [707 DIGGING, TRANSPORTING, PLANTING AND ESTABLISHMENT OF TREES, SHRUBS AND VINES](#) for the applicable Planting Suitability Zone of Illinois.

All plantings shall be mulched unless specified otherwise in a landscaping or planting plan following criteria in practice standard [MULCHING 875](#). The mulching material shall be uniformly graded and have the ability to completely block sunlight from reaching the surface of the soil. Mulching materials shall meet the minimum requirements as listed in material specifications [592 GEOTEXTILE](#), [800 PAPER AND PLASTIC NETTING](#), [801 JUTE NETTING](#), [802 EXCELSIOR BLANKETS](#), and [803 STRAW BLANKETS](#).

CONSIDERATIONS

Tree planting in urban areas should be completed as specified in a landscaping or tree and shrub planting plan developed for each site.

Care should be exercised to avoid locating trees and shrubs where they will, at maturity, interfere with electrical lines, utility maintenance zones, drain tiles, septic fields or create a traffic hazard due to blocked visibility.

Existing quality trees and shrubs should be evaluated and, where appropriate, incorporated into the landscaping or tree and shrub planting plan.

Trees and shrubs to plant should be selected based on:

1. Desired function such as shade, privacy or noise reduction screening,

2. Plant characteristics such as hardiness, growth rate, mature height and spread, resistance to insect, disease and pollution, seed production habits and soil or site requirements.

PLANS AND SPECIFICATIONS

Plans and specifications are to be developed for specific planting sites in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose.

Installation for this practice shall meet the requirements as listed in construction specification [707-DIGGING, TRANSPORTING, PLANTING AND ESTABLISHMENT OF TREES, SHRUBS AND VINES](#).

All plans shall include the installation, inspection, and maintenance schedules with the responsible party identified.

Standard drawing [IL-686 TREE AND SHRUB PLANTING SITE PLAN](#) may be used as the planting plan for a specific site.

OPERATION AND MAINTENANCE

A maintenance program shall be established to provide sufficient water, fertility, mulch, corrective pruning and protection from damage by insects, diseases and machinery. Dead or severely damaged plants will be replaced as needed.

NRCS IL August 1994

urbst985.doc

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

TREE PROTECTION

(no.)
CODE 990

(Source: USDA - Natural Resources Conservation Service - Illinois)

DEFINITION

The protection of individual trees from damage during construction operations.

PURPOSE

The purpose of this practice is to reduce damage to and loss of individual trees during construction by implementing pre- to post-construction tree protection procedures.

CONDITIONS WHERE PRACTICE APPLIES

This practice applies on development sites containing individual trees. Refer to practice standard [TREE AND FOREST ECOSYSTEM PRESERVATION 989](#) for information on preserving stands of trees.

CRITERIA

The Critical Root Zone (CRZ) is one foot outside the perimeter of the leaf canopy of the tree to be protected. This area shall be protected from damage during construction operations. Trees not

identified to be protected shall be removed.

All required protection measures shall be installed prior to the commencement of any site development activity and shall remain in place and in working, functional order until all site development activities have ceased or the surrounding area has been stabilized.

No construction activities, including the placement of topsoil, shall be permitted within the CRZ. In addition, all roadways, parking areas, and storage areas shall be located outside any CRZ.

Construction fencing (fluorescent polyethylene laminar safety netting), wooden snow fence, or approved equivalent with a minimum height of 40 inches shall be installed around the CRZ of all trees to be protected, prior to pruning. The fencing shall be secured to ground-mounted metal or wood posts spaced a maximum of 6 feet apart and maintained to prevent clearing, grading

and development activities from encroaching within the CRZ.

If a higher degree or more permanent protection is desired a chain link fence following criteria in Construction Specification [91 CHAIN LINK FENCE](#), a wire fence following criteria in Construction Specification [92 FIELD FENCE](#), or a comparable wooden structure may be used.

Signs shall be posted that identify the fenced areas as CRZ.

Appropriate soil erosion and sediment control measures shall be installed outside the CRZ to prevent sediment from reaching the CRZ.

Locate roadways, storage areas, parking pads, etc. at least 25 feet from the CRZ of an individual tree.

Follow natural contours, where feasible to maintain the natural drainage patterns of the site so as not to cause the tree to get reduced moisture.

Do not trench within the CRZ of the protected tree. For roots impacted outside the CRZ, the roots shall be properly pruned according to the Society of American Foresters, National Arborist Association and International Society of Arboriculture standard of using the appropriate pruning tool to make a clean cut. The use of heavy equipment such as a backhoe for tree root pruning shall be prohibited.

In situations where it is not feasible to avoid impact in the critical root zone, follow criteria in practice standard [TREE PROTECTION - AUGERING 991](#).

CONSIDERATIONS

When working within the boundary of a municipality, local authorities such as the Urban Forester, City Arborist, Municipal Forester or Horticulturist, or Public Works officials should be contacted to determine locally enforced tree protection/preservation standards.

A professional forester or certified arborist should be consulted for any clearing of trees and any actions that deviate from criteria within this standard. On-site supervision is recommended.

Trees to be saved should be evaluated using the following criteria in priority order:

1. Species and condition (maintain slower growing trees in good condition),
2. Long-term suitability of the tree for its present location,
3. Length of time to mitigate losses,
4. Cost of mitigating tree losses,
5. Expected long-term maintenance costs for the tree compared to other trees of the same age/size,
6. Soil erosion prevention and reduction of storm water runoff,
7. The number of other trees growing under the same conditions and the precedent that would be set by removing the tree in question,
8. Impact on property value and aesthetics,
9. Ability to screen noise and visual improprieties or ability to enhance privacy, and
10. Ability to moderate temperature changes, provide shade and reduce wind forces.

Trees to be removed should be evaluated using the following criteria in priority order:

1. In the opinion of the professional forester or certified arborist, there is a clear and reasonable risk of failure that could cause injury or property damage including existing utility service and corrective measures are not feasible and/or the tree is a safety hazard.
2. Tree is dead.
3. The tree is in poor condition with several dead branches or major crack(s).
4. Contiguous and fatal disease is present as diagnosed by a trained entomologist, plant pathologist or professional forester.
5. Current tree damage is beyond repair or the tree is in extremely poor shape due to storm damage or previous mechanical injury.
6. There is a potential of the tree to damage existing or future hardscape features such as driveways or sidewalks.
7. There is no feasible way to avoid disturbing the soil around, grading over, or placing a hardened surface within the critical root zone and the tree is an oak, hickory, red bud, horse chestnut, Kentucky coffee tree, larch, honey locust, or conifer. Consultation with a professional forester is required prior to using this criteria for tree removal.
8. Tree has a greater than 45 degree lean toward traffic or another target or it creates an unsafe vision clearance for pedestrians or vehicular traffic.
9. Tree is a fast growing or a weak wooded tree that is invasive such as box elder, silver maple, tree of heaven, Russian olive or black

cherry. Exceptions may be made for large healthy specimens of these species.

10. Tree is within five feet of a structure or that when mature will have a canopy spread that will overlap the structure. Consult with an arborist or forester.
11. The tree could be successfully transplanted with a tree spade onto another site.
12. Trees that are non-native species or invasive.

A mitigation plan for damaged trees should be prepared in consultation with a professional forester or certified arborist and included with construction plans and contract documents.

When site soil resources have been greatly altered, it is recommended a soil restoration strategy be implemented. The strategy may include:

1. Scarifying compacted areas
2. Adding top soil in areas of extreme erosion
3. Adding about 12 inches of well-rotted leaf compost
4. Adding ground cover using herbaceous vegetation, shrubs, and trees. Use of native species is encouraged.

PLANS AND SPECIFICATIONS

Plans and specifications for tree protection shall be in keeping with this standard and will describe the requirements for applying the practice. At a minimum include the following items:

1. All existing trees by species, location, and diameter at 4 ½ feet above the ground and clearly

indicate the trees and/or branches to be removed.

2. Locations of roadways, storage areas, truck clean-out areas, and parking pads, in relationship to the trees to be protected.
3. Location and type of fencing to be used to protect trees, including the distance for placing the fencing around the CRZ.
4. Types and locations of signs.

All plans shall include the installation, inspection, and maintenance schedules with the responsible party identified.

Standard drawing [IL-690 TREE PROTECTION - FENCING](#) may be used as the plan sheet.

OPERATION AND MAINTENANCE

The protective signs and fences will be removed only after all construction work has been finished, including final grading and shaping of the site, and the site has been inspected by a professional forester for damages to the trees.

On active construction sites, it is recommended that trees be inspected every 7 days for compliance.

Inspections shall include a listing of trees with:

1. Damage to trunks
2. Mounding of soil around the trunk
3. Evidence of root damage
4. Evidence of improper pruning

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

TREE PROTECTION - AUGERING

(no.)
CODE 991

(Source: Tree City USA Bulletin No. 35)

DEFINITION

Underground construction such as utility work by augering (tunneling) through an individual tree's Critical Root Zone (CRZ).

PURPOSE

The purpose of this practice is to reduce damage to and loss of individual trees where underground construction involves a tree's CRZ.

CONDITIONS WHERE PRACTICE APPLIES

This practice applies on development sites containing trees, infrastructure including utilities, and a construction project that has limited space and where these elements are in direct conflict.

CRITERIA

The CRZ is one foot outside the perimeter of the leaf canopy of the tree to be protected. This area shall be protected from damage during construction operations.

All required protection measures shall be installed prior to the commencement of any site development activity and shall remain in working, functional order until all site development activities have ceased or the surrounding area has been stabilized. Protection measures, including fencing and signage, shall follow criteria in practice standard [TREE PROTECTION 990](#).

Open trenching in the root zone of a tree is prohibited except when the trenching falls outside the CRZ.

All trees located where there is insufficient space to bypass the CRZ must be augered. Augering activity shall not occur on more than one side of the tree and shall follow distance and depth requirements in Table 1.

TABLE 1
AUGERING REQUIREMENTS

Tree Diameter (in.)	Distance of Augering from Tree Trunk - each side (ft.)	Depth of Augering (ft.)
1-4	3	2 ½
5-9	6	3
15-19	10	3 ½
20 inches or more	15	4

The following shall be avoided:

1. Making deep cuts that sever a large portion of the root system, depriving the tree of water and increasing the tree's chance of wind throw.
2. Compacting the soil within the area not designated for augering.
3. Any other actions, such as depositing concrete wash, which hardens the surface area within 25 feet of the CRZ.

CONSIDERATIONS

When working within the boundary of a municipality, local authorities such as the Urban Forester, City Arborist, Municipal Forester or Horticulturist, or Public Works officials should be contacted to determine locally enforced tree tunneling or augering requirements.

It is recommended that a professionally qualified individual check the area work plan and site for environmental soundness and evaluate the techniques for protecting the trees.

A mitigation plan for damaged trees should be prepared in consultation with

a professional forester or certified arborist and included with the construction plans and contract documents.

When site soil resources have been greatly altered, it is recommended that a soil restoration strategy be implemented. The strategy may include:

1. Scarifying compacted areas
2. Adding top soil in areas of extreme erosion
3. Adding about 12 inches of well-rotted leaf compost
4. Adding ground cover using herbaceous vegetation, shrubs, & trees. Use of native species is encouraged.

PLANS AND SPECIFICATIONS

Plans and specifications for augering operations shall be in keeping with this standard and will describe the requirements for applying the practice. At a minimum include the following items:

1. The individual trees to be protected and the location of the proposed auger tunnel.
2. The location and type of fencing to be used to protect trees indicating the distance for placing the fencing around the CRZ.
3. Locations of roadways, storage areas, truck clean-out areas, and parking pads, in relationship to the trees to be protected.
4. Types and locations of signs

All plans shall include the installation, inspection and maintenance schedules with the responsible person clearly identified.

OPERATION AND MAINTENANCE

NRCS IL April 2000

urbst991.doc

The protective signs and fences will be removed only after all construction work has been finished, including final grading and shaping of the site, and the site has been inspected by a professional forester for damages to the trees.

It is recommended that on-site inspections be conducted to determine compliance with augering specifications.

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

VEGETATIVE STREAMBANK STABILIZATION

(ft.)
CODE 995

(Source: USDA – Natural Resources Conservation Service – Illinois)

DEFINITION

The stabilization and protection of eroding streambanks with selected vegetation.

PURPOSE

The purpose of this standard is to protect streambanks from the erosive forces of flowing water and provide a natural, pleasing appearance.

CONDITIONS WHERE PRACTICE APPLIES

This practice applies to natural or excavated channels where the streambanks are susceptible to erosion from the action of water, ice or debris and the problem can be solved using vegetative measures.

Vegetative stabilization is generally applicable where bankfull flow velocity does not exceed 5 ft/sec. and soils are erosion resistant. Above 5 ft/sec., structural measures are generally required.

CRITERIA

The U.S. Army Corps of Engineers, Illinois Department of Natural Resources-Office of Water Resources, Illinois Environmental Protection Agency, and any appropriate local unit of government shall be consulted for determining permits that may be required.

Vegetative protective measures to be applied shall be compatible with improvements planned or being carried out by others.

Protective measures shall be started at a stabilized or controlled point on the stream and extended to a stabilized or controlled point downstream. The grade of the channel must be controlled, either by natural or artificial means, before any vegetative protective measures can be considered feasible unless the live dormant posts or stakes can be installed below the anticipated depth of bottom scour.

Cuttings, stakes and posts to be used as live dormant woody materials shall be obtained from moisture-loving species that will either root naturally or respond to treatment with rooting hormones as listed in Table 3. All woody plant materials will be dormant at the time of installation. Establishment dates and procedures shall conform to those listed in construction specification 750 and standard drawing No. 695-VEGETATIVE STREAMBANK STABILIZATION SITE PLAN.

Establishment dates and procedures for vegetative streambank stabilization using selected grasses or grass mixtures shall conform to those listed in Table 1 and Table 2.

Bank reshaping and disturbance will be kept to a minimum except where necessary to adequately install the practice and meet any appropriate requirements. If deemed needed, banks will be shaped to result in a bank slope of 1:1 or flatter.

A temporary seeding shall be used on all sites using a mixture and seeding rates as listed in Table 1 to provide temporary protection while the permanent cover is becoming established. Planting dates shall be as shown in Table 2.

The use of an EROSION BLANKET meeting requirements in practice standard 830 will provide additional protection during the establishment period.

Where necessary, structural measures shall be planned along with the vegetative measures to stabilize the streambanks using practice standard STRUCTURAL STREAMBANK

STABILIZATION 940 and any applicable construction and material specifications and standard drawings.

CONSIDERATIONS

Special attention should be given to improving wildlife habitat as a secondary benefit by using woody plants and grasses that provide food and/or cover for native wildlife species.

The retention of a 30 feet riparian zone along stream channels that is established to trees, shrubs, and/or grasses may provide wildlife, landscaping and water quality benefits.

Streambanks to be protected using grasses may need to be shaped on a 2:1 or 3:1 slope to provide for adequate seedbed preparation. The use of sod, instead of seeding, should be evaluated where economically justified and technically feasible.

The type of vegetative cover to be used should be based on the soil type, stream velocities, adjacent landuse and anticipated level of maintenance to be performed.

Steep channel reaches, high erosive banks and sharp bends may require structural stabilization measures, such as riprap, while the remainder of the streambank may require vegetative measures, only.

PLANS AND SPECIFICATIONS

Plans and specifications are to be developed for specific planting sites in keeping with this standard and shall describe the requirements for applying the practice to achieve its intended purpose.

Installation of this practice shall meet the requirements as listed in construction specification 750 - USE OF DORMANT WOODY PLANTS FOR STREAMBANK STABILIZATION, construction specification 751 - USE OF GRASSES FOR STREAMBANK STABILIZATION, and standard drawing No. 695 - VEGETATIVE STREAMBANK STABILIZATION SITE PLAN which may be used as the planting plan for a specific site.

OPERATION AND MAINTENANCE

A maintenance program shall be established to provide sufficient moisture, fertility, replacement of dead or damaged plants and protection from damage by insects, diseases, machinery and human activities.

Streambanks stabilized using grasses will be evaluated as to whether an occasional or periodic mowing and fertilization are to be performed to maintain a healthy protective ground cover.

NRCS IL August 1994

TABLE 3

WOODY PLANT MATERIALS

<u>Plant Zone</u>	<u>Common Name</u>	<u>Genus Species</u>	<u>Growth Form</u>
1	Black Willow	Salix nigra	Tree
1	Bankers Willow	Salix cottettii	Shrub
1	Purple-osier Willow	Salix purpurea	Shrub
1	Sandbar Willow	Salix interior	Tree
1	Carolina Willow	Salix caroliniana	Tree
1	Peach-leaved Willow	Salix amygdaloides	Tree
1	Buttonbush	Cephalanthis occidentalis	Shrub
1,2,3	Red-osier Dogwood	Cornus stolonifera	Shrub
2,3	Silky Dogwood	Cornus amomum	Shrub
2,3	Flowering Dogwood	Cornus florida	Tree
2,3	Green Ash	Fraxinus pennsylvanica	Tree
2,3	Sycamore	Platanus occidentalis	Tree
1,2,3	Baldcypress	Taxodium distichum	Tree
1,2	River Birch	Betula nigra	Tree
1,2,3	Eastern Cottonwood	Populus deltoides	Tree
1,2,3	Swamp Cottonwood	Populus heterophylla	Tree

Species selection shall consider the position of the plant in the bank profile (see figure 2 of standard drawing).

Zone 1 = Below normal waterline to upper limit of saturation area kept moist by capillary water movement. This zone includes the greatest potential for periodic inundations and the least moisture stress.

Zone 2 = Area from upper limit of Zone 1 to 2-3 feet from the top of the bank. This area may be subject to rapid drying and greater moisture stress.

Zone 3 = Area 2-3 feet below the top of the bank to a minimum of 30 feet into the floodplain (riparian area).

NATURAL RESOURCES CONSERVATION SERVICE
ILLINOIS URBAN MANUAL
PRACTICE STANDARD

WELL DECOMMISSIONING

(no.)
CODE 996

(Source: IL Department of Natural Resources)

DEFINITION

The sealing and permanent closure of a water well, boring, or monitoring well.

PURPOSE

The purposes of this practice are to:

1. Prevent entry of contaminated surface water into the well and migration of contaminants into the unsaturated (vadose) zone or saturated zone.
2. Prevent entry of vermin, debris, or other foreign substances into the well or well bore hole.
3. Eliminate the physical hazard of an open hole to people, animals and vehicles.
4. Prevent the commingling of chemically or physically different ground waters between separate water bearing zones.

CONDITIONS WHERE PRACTICE APPLIES

This standard applies to sealing and permanent closure of a water well, boring, or monitoring well that is no longer in use, or is in such a state of disrepair that it has the potential for transmitting contaminants into an aquifer or otherwise threatens the public health or safety.

This practice does not apply to wells that were used for waste disposal, or if evidence of contamination in the well exists. This practice does not apply to wells that contain contaminant levels that exceed state or federal water quality standards. Treatment of contamination source(s) is required before a well is decommissioned.

CRITERIA

All planned work shall comply with regulations as set forth in the Illinois Water Well Construction Code (Section 920.120 - Abandoned Wells and Section

920.130 - Permit Requirements) and any applicable local law.

CONSIDERATIONS

The decommissioning of water wells, borings, and monitoring wells are regulated by the Illinois Water Well Construction Code and local health department ordinances. If there is any disagreement between this standard and the current state/local codes, the state/local codes have primacy.

This practice may be part of a ground water protection system that includes water and chemical management practices.

To the extent practicable, an abandoned well should be decommissioned in a manner that restores the original hydrogeological conditions of the well site and does not preclude the use of the site from future land management practices.

Decommissioning requires special consideration of specific geological, biological, physical, and climatic conditions, the chemical composition of the surrounding soil, rock, and ground water at the well site, and the well's construction. The proximity of the abandoned well to other planned or existing wells and the hydrologic conditions of the area should be considered when decommissioning abandoned wells.

PLANS AND SPECIFICATIONS

Plans and specifications for decommissioning abandoned water wells shall be consistent with this standard and shall describe the

requirements for applying the practice to achieve its intended purposes.

Minimum documentation of a well decommissioning shall consist of an approved (by Illinois State Department of Health or local health department) plan or permit and a well sealing form (IL 482-0631, or local health department provided form).

OPERATION AND MAINTENANCE

The decommissioned well site shall be maintained in such a manner as to be consistent with adjacent land use(s). If general subsidence of the area overlaying the sealed well occurs, sufficient soil material shall be added to maintain a positive slope away from the abandoned well.

NRCS IL November 1999

urbst996.doc

SECTION 5 - CONSTRUCTION SPECIFICATIONS

INTRODUCTION

This section contains construction specifications and instructions for their use. The construction specifications along with material specifications (see Section 6) make up the contract specifications and can be used as the requirements in construction contracts. To make the construction specifications complete the last section must be written to identify the specific methods that apply, identify and describe bid items, and list any specific instructions that pertain to the job under construction. This last section is normally shown with the heading ITEMS OF WORK AND CONSTRUCTION DETAILS.

The construction specifications and instructions for use are from NRCS's National Engineering Handbook Series (NEH) Part 642 (formerly referred to as NEH Section 20) as well as several state interim specifications. The interim specifications are numbered starting at 200 and do not usually have a corresponding instruction for use.

A general discussion is included that describes how a bid schedule is set up, how construction specifications are compiled, and how construction details and bid items are set up in the specifications. Some examples are included in the discussion. The discussion is an abridged version from NEH Part 642.

Current updates of construction specifications from NRCS's National Engineering Handbook Series Part 642 can be found at <http://www.ftw.nrcs.usda.gov/nehcs.html>. The notice for the May 2001 release of the construction specifications in Part 642 identified revisions to Construction Specification 51 - Corrugated Metal Pipe and Construction Specification 94 - Contractor Quality Control. These changes are reflected in this release of Chapter 5 of the Illinois Urban Manual. The dates on the other construction specifications have not been updated; however, the technical content of all other construction specifications has not likely changed.

This section was updated in November 2002.

NRCS IL November 2002

(This page was intentionally left blank)

SECTION 5 - CONSTRUCTION SPECIFICATIONS

GENERAL DISCUSSION

CONSTRUCTION CONTRACT

The body of a construction contract consists of general provisions, a bid schedule, specifications, drawings, inspection requirements, performance time, contract administration data and, when applicable, special provisions and wage rate decisions. Typically the general provisions are administrative and technical requirements that apply to all items of construction and to all contracts. The bid schedule tabulates the items of work for which direct payment will be made, shows the estimated quantities of work and the units of measurement, and provides space for the entry of contract prices. The specifications and drawings include the technical details and requirements of the contract. The office responsible for the design of the work develops the drawings and specifications and, in cooperation with the responsible administrative office, the bid schedule. The special provisions are administrative instructions and requirements that apply to the specific contract and are prepared by the responsible administrative office.

TERMS AND DEFINITIONS

The following terms and definitions are used relative to specifications for construction contracts:

National Standard Construction Specifications state the technical and workmanship requirements for the various operations required in the construction of the works, the methods of measurement, and the basis of payment.

National Standard Material Specifications state the quality of materials to be incorporated in the permanent works. The material specifications make up Section 6 of this manual.

Interim Specifications are specifications prepared for use in contracts that include construction items or materials not covered by National Standard Specifications.

Standard Specifications are National Standard and Interim specifications.

Construction Details are prepared by the design office and state the special requirements peculiar to a specific work of construction. They may take the form of written addenda to the standard construction specifications or notes on the drawings.

Contract Specifications are the complete specifications prepared for a specific contract and consist of construction and material specifications supplemented by lists and descriptions of items of work and construction details.

NATIONAL STANDARD CONSTRUCTION SPECIFICATIONS

National standard construction specifications are to be used verbatim. Some national standard specifications have sections that contain alternative methods of achieving work. The specification writer may delete the methods not used in the contract;

however, the method selected must be used verbatim. Only methods identified in the specification may be deleted from the national standard construction specification. Each of the national standard construction specifications is supplemented by instructions for its use. These instructions state the applicability of the specification and discuss the items of information that must be included in the contract specifications and drawings in order to completely define the specified item. They also discuss the conditions under which it may be appropriate to use any of the various methods listed. These instructions are included for use by design personnel and are not to be included in contract specifications.

NATIONAL STANDARD MATERIAL SPECIFICATIONS

National standard material specifications have been prepared for those materials whose quality must be uniform in all areas of applicability. National standard material specifications are to be used verbatim. They are not supplemented by instructions for use. Items of information that must be included in the contract specifications in order to completely describe the materials required for a specific contract are listed in the instructions for use of the construction specifications to which the material specifications are complementary.

Reference to material specifications may be in national standard construction specifications or may be placed in the construction details (either written in the specifications or noted on the contract drawings).

INTERIM SPECIFICATIONS

Interim specifications are for items that are not covered by national standard construction and material specifications. Interim specifications follow the same format as the national standard specifications. They are typically unique to a specific locality and therefore are not national in scope.

SELECTING APPROPRIATE STANDARD SPECIFICATIONS

The type of work to be done or the type of structural detail required will often dictate the construction method or sequence. The specification requirements must be compatible with the methods that must be used. The specification writer must also make sure that the methods selected in one specification are compatible with those selected in another. For example, the method of designating pay limits for excavation and earthfill.

BID SCHEDULE

The bid schedule forms the basis for payments to the Contractor and must list all items of work for which direct payment will be made. Since the efficiency of contract administration is directly affected by the manner in which the schedule is organized, the preparation of the bid schedule requires the close cooperation of the responsible design engineer and the contracting officer. Operating procedures must include provision for administrative review of the bid schedule in the early stages of its development as well as upon completion.

Designating the Items of Work

Considerable judgment based on design, construction, and contracting experience is required to divide the work into items for inclusion in the bid schedule. The schedule must be sufficiently comprehensive to allow the Contractor to make reasonably accurate estimates of the cost of doing the work and to enable the Contracting Officer to keep orderly records of work progress and to accurately compute progress and final payments due; on the other hand, the number of scheduled items should be held to the minimum needed to accomplish these purposes. The practicable extent to which the work should be divided into scheduled items must be judged in light of the quantities of work involved and local construction practices and procedures. The bid schedule should include those items necessary to result in fair and equitable treatment of the owner(s) and the Contractor.

Division of the Work into Items

For maximum efficiency of contract administration, the work should be divided into items on the basis of the following principles:

1. The work should be divided into items in a manner that will insure reasonable refinement of unit prices. The cost of any given type of work will vary according to its complexity and the complicating effects of the conditions under which it must be done. Generally, the scope of a bid item should be limited to a given type of work of a particular order of complexity and cost.

Exceptions to this rule may be justified on small jobs involving relatively small quantities of work.

2. The work should be divided into items in a manner that will prevent confusion of supplemental job requirements. Similar types of work may involve different sizes of components or different qualities of materials. To prevent confusion, each variation of a given type of work should be established as a separate item of work. Also, the grouping of non-related items or similar components of separate works of improvement should be avoided.
3. The work should be divided into items in a manner consistent with the cost sharing arrangements established in the work plan and the project agreement. For many projects, certain works of improvement may be paid for entirely or partially by different sponsoring organizations. To facilitate accounting of project costs, the work for such improvements should be established as separate items of work in the bid schedule.

Numbering and Titling

Bid items must be numbered consecutively beginning with the number one (1). Sub-item numbers shall not be used. Each bid item shall be given a descriptive title that distinctly identifies the work to be done. All items that involve significant quantities of

work (or significant procurement cost in the case of prefabricated units) should be designated as separate bid items.

Pay Items

Measurable items whose quantities may be subject to variation should be designated for payment on a unit price basis, and the estimated quantity of work and units of measurement must be shown in the schedule. Items that involve significant quantities of work, but are not conveniently measurable or whose quantities are not subject to variation, may be designated for payment on a lump-sum basis. An item involving a relatively insignificant quantity of work that is subject to only very minor variation may be designated as a subsidiary item, compensation for which is included in the payment for another item which has a logical relationship to the subsidiary item. Subsidiary items will not be numbered nor listed in the bid schedule, but must be designated and described in the "Items of Work and Construction Details" of the item and also referenced in the "Items of Work and Construction Details" Section of the specification for the pay item to which it is subsidiary.

Units of measurement must be compatible with the measurement and payment clauses of the specifications.

Example 1

A typical bid schedule format is demonstrated by the following:

<u>BID SCHEDULE</u>						
<u>Item</u>	<u>Work</u>	<u>Spec No.</u>	<u>Estimated Quantity</u>	<u>Unit</u>	<u>Unit Price</u>	<u>Amount</u>
1	Clearing, Class A	1	12.5	ac.	_____	_____
2	Mobilization and Demobilization	8	1	Job	<u>xxxx</u>	_____
3	Excavation, Common	21	300	cu. yd.	_____	_____
4	Loose Rock Riprap	61	500	ton	_____	_____

CONTRACT SPECIFICATIONS

Contract specifications shall consist of an assembly of the appropriate standard construction and material specifications. Each construction specification will be supplemented by a Section entitled: "Items of Work and Construction Details". The supplemental Section of each construction specification shall: (1) be prepared especially for each invitation; (2) designate by number and title all of the bid items (exactly as numbered and titled in the bid schedule) to be performed in conformance with the requirements of the specification; (3) designate all subsidiary items to be

performed in conformance with the requirements of the specification; (4) for each designated item of work, state such supplemental requirements and items of information as are needed to relate the construction specification to the job at hand; (5) bear the number that is next in sequence after the number of the last Section of the standard specification; and (6) be inserted into the contract specification as the last page(s) of the construction specification.

Compilation

A contract specification must conform verbatim to the standard construction or material specification except, in a Section for which the standard specification offers methods, not all of the methods need to be included in that Section of the contract specification or be a one-time-use specification. The methods selected must be compatible with one another and with the conditions, materials and methods prevalent in the area of applicability and the requirements of the specified structural element.

More than one method may be included in any Section of a construction specification, in which case, the methods shall be numbered sequentially (i.e., Method 1, Method 2, etc.). The method applicable to each respective item of work, material, measurement and payment shall be identified in the construction detail Section. The instruction for each construction specification identifies the optional methods and provides guidance on their use.

Identifying

The title of each contract specification shall be the same as that of the standard construction or material specification.

When a construction specification is modified for a specific job by deleting specific methods from the standard specification, the state abbreviation and project name shall be added below "NRCS-IL-URB" in the lower left corner to indicate to the user and reviewers that the standard specification has been modified. The date at the bottom of the pages of the national standard specification shall not be changed. The pages should be renumbered consecutively.

When a construction specification is not modified by deleting specific methods from the standard specification, the numbering and footer information on the standard specification shall not be changed.

The Items of Work and Construction Details pages shall have the state abbreviation and the project name below "NRCS-IL-URB" in the lower left corner, the same page numbering format as the standard specification centered at the bottom of the page, and the date of compilation in the lower right corner.

Measurement and Payment

Each construction specification contains a Section that describes the method measurement to be used for the work performed or the material furnished and the

manner of payment to be made in full compensation of the work described. The basis for designating separate work items was described earlier under the "Bid Schedule" Section. Within the conditions described therein, each of the construction specifications may be modified to include a lump sum payment method. The format and working of the method will generally be as follows:

For items of work for which specific lump sum prices are established in the contract, the quantity of work will not be measured for payment. Payment for this item will be made at the contract lump sum price for the item and will constitute full compensation for completion of the work.

Preparing Construction Details

The construction details for each item of work should be concise and will normally contain (see individual instruction for use of each construction specification):

1. Such definitions and descriptions as are needed to define the scope of work;
2. The information required to define the types and qualities of materials to be used in the work;
3. Special requirements such as foundation preparation, grading tolerances, provisions for coordinating with other work, obtaining "As Built" geology data, etc.; and
4. Other items of instruction necessary to define the construction requirements peculiar to the item of work.

The construction details should contain only such information and instructions as are needed to relate the construction specification to the job at hand. It is neither necessary nor desirable to emphasize or attempt to interpret provisions of the specification by repetition of the provisions in the construction details in the same or similar words.

In preparing construction details, it must be recognized that notes on the drawings have the effect of specifications in defining the type and quality of materials to be furnished and in defining the scope of the work. Supplemental information or requirements that are directly related to details shown on the drawings may be stated in notes on the drawings rather than in the specifications if that arrangement will more conveniently and effectively convey the information to the appropriate individuals that will benefit from this data. The engineer responsible for the design must use good judgment in deciding where various supplemental data should be located for maximum effectiveness. Usually, information shown by notes on the drawings need not be repeated in the specifications, however, if there is a compelling reason for doing so, great care must be taken to prevent conflicts between the notes and the specifications.

Construction details should not conflict with or interpret the general terms and conditions of the contract. They may modify a clause in the standard specifications if the standard specification contains the phrase "unless otherwise specified...".

Example 2

The following example demonstrates a typical construction detail for excavation that would be prepared for a specific contract and inserted at the end of Construction Specification 21, Excavation:

11. ITEMS OF WORK AND CONSTRUCTION DETAILS

Items of work to be performed in conformance with this specification and construction details are:

a. Bid Item 7, Excavation, Foundation, Common

- (1) This item shall consist of the excavation of unsuitable materials from the foundation of the main dam in areas that are located within the base area of the dam but outside the limits of cutoff trench.
- (2) The depth of excavation required is estimated at five (5) feet at the central half of the base area of the dam and tapering to about two (2) feet at the edges. The actual depths and extent of foundation excavation will be determined by the engineer after examination of the material encountered.
- (3) The sides of all foundation excavations shall not be steeper than 1 -1/2 horizontal to 1 vertical.
- (4) In Section 5, Use of Excavated Materials, Method 1 will apply.
- (5) In Section 6, Disposal of Waste Materials, Method 2 will apply.
- (6) In Section 11, Measurement and Payment, Method 1 will apply.

b. Bid Item 8, Excavation, Cutoff Trench, Common

- (1) This items consists of all common excavation required within the limits of the cutoff trench as shown on the drawings.
- (2) The depth of excavation required is estimated to extend generally down to near elevation 1105. The actual depths of excavation will be determined by the engineer after examination of the materials encountered.
- (3) In Section 5, Use of Excavated Materials, Method 1 will apply.
- (4) In Section 6, Disposal of Waste Materials, Method 2 will apply.
- (5) In Section 11, Measurement and Payment, Method 1 will apply.

c. Bid Item 9, Excavation, Cutoff Trench, Rock

- (1) This item consists of all rock excavation required within the limits of the cutoff trench as shown on the drawings.
- (2) In Section 4, Blasting, a blasting plan shall be furnished to the Contracting Officer for review and approval prior to the start of any blasting operations.
- (3) In Section 5, Use of Excavated Materials, Method 1 will apply.
- (4) In Section 6, Disposal of Waste Materials, Method 2 will apply.
- (5) In Section 11, Measurement and Payment, Method 1 will apply.

d. Bid Item 10, Excavation, Principal Spillway, Common

- (1) This item consists of all common excavation required within the limits shown on the drawings for the installation of the pipe conduit, riser footing, and outlet structure, except for that portion of the excavation located within the limits of the cutoff trench or above the lower limit of foundation excavation.
- (2) In Section 5, Use of Excavated Materials, Method 1 will apply.
- (3) In Section 6, Disposal of Waste Materials, Method 2 will apply.
- (4) In Section 11, Measurement and Payment, Method 1 will apply.

e. Bid Item 11, Excavation, Principal Spillway, Rock

- (1) This item consists of all rock excavation required within the limits shown on the drawings for the installation of the pipe conduit, riser footing, and outlet structure except for that portion of the excavation located within the limits of the cutoff trench.
- (2) In Section 4, Blasting, a blasting plan shall be provided to the Contracting Officer for review and approval prior to the start of any blasting operations.
- (3) In Section 5, Use of Excavated Materials, Method 1 will apply.
- (4) In Section 6, Disposal of Waste Materials, Method 2 will apply.
- (5) In Section 11, Measurement and Payment, Method 2 will apply.

f. Bid Item 12, Excavation, Emergency Spillway, Common

- (1) This item consists of all common excavation required within the limits shown on the drawings for the construction of the emergency spillway.
- (2) The grading tolerances for emergency excavation control section (Emergency Spillway Stations 11+30 to 12+10) shall be plus or minus 0.1 foot from grade shown. The grading tolerances for other emergency spillway excavations shall be plus or minus 0.2 feet from the grades shown
- (3) In Section 5, Use of Excavation Materials, Method 1 will apply.
- (4) In Section 6, Disposal of Waste Materials, Method 2 will apply.
- (5) In Section 11, Measurement and Payment, Method 1 will apply.

g. Subsidiary Item, Excavation, Borrow, Common

- (1) This item consists of all common excavation required to obtain suitable earthfill materials required to construct the permanent works.
- (2) In Section 9, Borrow Excavation, all borrow areas shall be graded to prevent the ponding of water. Finished slopes shall not be steeper than four (4) horizontal to one (1) vertical.
- (3) In Section 11, Measurement and Payment, no separate payment will be made for borrow excavation. Compensation for borrow excavation will be included in the payment for Bid Item 13, Earthfill Zone 1.

Example 3

The following example demonstrates a typical construction detail to cross-reference a subsidiary item, for earthfill that would be written for a specific contract and inserted into Construction Specification 23, EARTHFILL. Refer to item g, Example 2 previously provided:

10. ITEMS OF WORK AND CONSTRUCTION DETAILS

Items of work to be performed in conformance with this specification and construction details are:

a. Bid Item 13, Earthfill, Zone I

- (1) This item consists of placing and compacting all suitable materials required to construct Zone I of the embankment and the desilting pond, it also includes backfilling the cutoff trench and constructing a two (2) foot thick blanket on the left abutment as shown on the drawings.
- (2) In Section 2, Materials, the following shall apply:
 - (a) The material for Zone I shall be the natural deposits of gravel, sands, silts, and clays obtained from borrow area 1 and suitable materials from the required excavations.
 - (b) Material selected to construction Zone I, Earthfill, shall contain not less than thirty-five (35) percent fines (material passing the No. 200 sieve) when determined on a dry weight basis of the portion of the mass smaller than three (3) inches in nominal diameter, when tested in accordance with ASTM D 1140.
 - (c) Unsuitable or oversize materials shall be removed from fill materials before placement on the embankment and shall be wasted in the designated disposal locations shown on the drawings. Acceptable rock materials larger than six (6) inches in diameter shall be removed from Zone I and placed in Zone II or placed as rock riprap as applicable.
- (3) In Section 4, Placement, the fill shall be placed in layers not exceeding nine (9) inches in thickness prior to compaction. The maximum size of rock incorporated in the fill matrix shall be six (6) inches.
- (4) In Section 5, Control of Moisture, the moisture content of the fill matrix at the time of compaction shall be maintained with the range of two (2) percentage points below to two (2) percentage points above optimum moisture content.
- (5) In Section 6, Compaction, compaction shall be Class A. The fill matrix shall be compacted to at least ninety-five (95) percent of the maximum density determined by compaction tests of the fill materials by the appropriate method outlined in ASTM D 698.
- (6) In Section 9, Measurement and Payment, Method 2 and 6 will apply. Such payment will constitute full compensation for related subsidiary Item, Excavation, Borrow, Common.

urbcsls2.doc

INSTRUCTIONS FOR USE OF CONSTRUCTION SPECIFICATION 1

CLEARING

1. APPLICABILITY

Construction Specification 1 is applicable to the clearing of vegetation at construction sites where grubbing is not required.

2. MATERIAL SPECIFICATIONS

There are no material specifications complementary to Construction Specification 1.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. When the area(s) to be cleared is definable on the project layout map or other construction plan view drawing, the limits of each Class (A, B, or C as defined in Section 2. CLASSIFICATION) of clearing must be shown and clearly defined.
- b. When the area(s) to be cleared are not definable on the drawings (which may occur for many channel improvement projects) the extent of each Class of clearing required must be described by notes and designation of right-of-way boundaries and station limits. The full extent of work to be performed must be clearly defined.
- c. When replacement plants are required because of damage caused by the Contractor, the specific size, number, and species needs to be specified in Section 8. Example: "Any tree removed that was designated to remain or is irreparably damaged shall be replaced with two 15 gallon size Valley Oak (*Quercus lobata*) as directed by the Contracting officer."
- d. When measurement and payment is identified to be in accordance with Method 2, Section 7, the survey line(s) along which the length of cleared area(s) is to be measured must be designated. The lateral extent and station reaches of the area(s) to be cleared must be clearly defined.
- e. Areas in which disposal of refuse/waste material will not be allowed or areas where disposal will be restricted or limited must be clearly defined or shown on the drawings.
- f. Required minimum depth of earth cover over buried materials, if applicable.
- g. Required surface grading over buried materials, if applicable. Existing natural flow patterns onto or from the construction site onto other properties must be a consideration in the final grading.
- h. Restrictions on the use of explosives, if any.
- i. Restrictions on the burning of combustible materials as a disposal procedure, if any.

- j. Special requirements to control erosion, water pollution, and air pollution, if applicable. Requirements of this specification must be compatible with any and all requirements outlined in Construction Specification 5, [Pollution Control](#), when included as part of the contract.
- k. Method(s) of measurement and payment, if the standard specification includes more than one method.

4. DISCUSSION OF METHODS

a. Section 7, Measurement and Payment

- (1) Methods 1 and 3 are intended for use when the area(s) to be cleared is/are extensive and can be defined in area units on the ground and clearly shown on the drawing(s). Section 8 should specify horizontal or surface measurements to be used to determine area cleared. A reservoir project is a good example of this type of site.
- (2) Method 2 is intended for use when the area(s) to be cleared is/are long and narrow, and cannot be clearly defined on the drawings. Section 8 should specify horizontal or surface measurements to be used to determine area cleared. A channel right-of way is a typical example of this type of site.
- (3) Method 4 is intended for use when the area(s) to be cleared cannot be measured practically and when it is reasonable to expect that variations in the quantity of clearing to be performed will be minor. For Method 4, the procedures that will be used to determine the amount of work satisfactorily completed for progress payment needs to be identified in Section 8.

Options may include:

- an on site agreed-to estimate of the percent of work satisfactorily completed at time of progress payment cut off; or
- require the contractor to provide measurements of all areas and those that have been satisfactorily cleared, and use a percentage of the total item; or other suitable and fair methods, one of which could be related to the construction schedule.

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

1. CLEARING

1. SCOPE

The work shall consist of the clearing and disposal of trees, snags, logs, brush, shrubs, stumps, and rubbish from the designated areas.

2. CLASSIFICATION

Unless otherwise specified in Section 8, clearing will be classified according to the following definitions:

Class A clearing requires that trees and other woody vegetation be removed so that the remaining stumps extend no higher than four (4) inches above the ground surface.

Class B clearing requires that trees and other woody vegetation be removed so that the remaining stumps extend no higher than twelve (12) inches above the ground surface.

Class C clearing requires that trees and other woody vegetation be removed as near the ground surface as conventional tools or field conditions will permit, or as specified in Section 8.

3. PROTECTION OF EXISTING VEGETATION

Trees and other woody vegetation designated to remain undisturbed shall be protected from damage throughout the entire construction period. Any damage resulting from the Contractor's operations or neglect shall be repaired by the Contractor.

Earthfill, stockpiling of materials, vehicular parking, and excessive foot or vehicular traffic shall not be allowed within the drip line of vegetation designated to remain in place. Vegetation damaged by any of these or similar actions shall be replaced with viable vegetation of the same species or as specified in Section 8 and approved by the Contracting Officer.

Any cuts, skins, scrapes or bruises to the bark of the vegetation shall be carefully trimmed and local nursery accepted procedures utilized to seal damaged bark.

Any limbs or branches one-half (1/2) inch or greater in diameter which are broken, severed or otherwise seriously damaged during construction shall be cutoff at the base of the damaged limb or branch flush with the adjacent limb or tree trunk.

All roots one (1) inch or greater in diameter which are cut, broken or otherwise severed during construction operations shall have the end smoothly cut perpendicular to the root. Roots exposed during excavation or other operations shall be covered with moist earth and/or backfilled as soon as possible to prevent the roots from drying.

4. MARKING

The limits of the areas to be cleared will be marked by means of stakes, flags, tree markings or other suitable methods. Trees to be left standing and uninjured will be designated by special markings placed on the trunks at a height of about six (6) feet above the ground surface.

5. CLEARING

All trees not marked for preservation and all snags, logs, brush, shrubs, stumps, rubbish and similar materials shall be cleared from within the limits of the marked areas.

6. DISPOSAL

All materials cleared from the designated areas shall be disposed of at locations shown on the drawings or in a manner specified in Section 8. The Contractor is responsible for complying with all local rules and regulations and the payment of any and all fees that may result from the disposal at locations away from the construction location.

7. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established in the contract, the cleared area will be measured to the nearest 0.1 acre. Payment for clearing will be made for the total area within the designated limits at the contract unit price for the specified class of clearing. Such payment will constitute full compensation for all labor, equipment, tools and all other items necessary and incidental to the completion of the work.

Method 2 For items of work for which specific unit prices are established in the contract, the length of the cleared area will be measured to the nearest full station (100 feet) along the line designated on the drawings or in the specifications. Payment for clearing will be made for the total length within the designated limits at the contract unit price for the specified class of clearing. Such payment will constitute full compensation for all labor, equipment, tools and all other items necessary and incidental to the completion of the work.

Method 3 For items of work for which specific unit prices are established in the contract, the cleared areas will be measured within the specified limits to the nearest 0.1 acre. The cleared areas will be determined by measuring the width cleared, within the specified limits, at representative sections and multiplying the average width between sections by the linear distance between sections. Payment for clearing will be made at the contract unit price for the item and shall constitute full compensation for all labor, equipment, tools and all other items necessary and incidental to the completion of the work.

Method 4 For items of work for which specific lump sum prices are established in the contract, payment for clearing will be made at the contract lump sum prices. Such payment shall constitute full compensation for all labor, equipment, tools and all other items necessary and incidental to the completion of the work.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 8.

INSTRUCTIONS FOR USE OF CONSTRUCTION SPECIFICATION 2

CLEARING AND GRUBBING

1. APPLICABILITY

Construction Specification 2 is applicable to the clearing and grubbing of woody vegetation and the removal of trash and rubbish at construction sites.

2. MATERIAL SPECIFICATIONS

There are no material specifications complementary to Construction Specification 2.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. When the area(s) to be cleared and grubbed, including area(s) of rubbish removal, is definable on the project layout map or other construction plan view, the limits must be shown and clearly defined.
- b. When the area(s) to be cleared and grubbed is not definable on the drawings (which may occur for many channel improvement projects) the extent of clearing and grubbing required must be described by notes and designation of right-of-way boundaries and station limits.
- c. When replacement plants are required because of damage caused by the Contractor, the specific size, number, and species needs to be specified in Section 7. Example; "Any tree removed that was designated to remain or is irreparably damaged shall be replaced with two 15 gallon size Valley Oak (*Quercus lobata*) as directed by the Contracting Officer."
- d. When measurement and payment is identified to be in accordance with Method 2, Section 6, the survey line(s) along which the cleared and grubbed area(s) length is to be measured must be designated. The lateral extent and station reaches of the area(s) to be cleared and grubbed must be clearly defined.
- e. Areas in which disposal of refuse/waste material will not be allowed or areas where disposal will be restricted must be clearly defined and/or shown on the drawings.
- f. Special requirements for grubbing depth, if required.
- g. Required depth of earth cover over buried materials, if applicable.
- h. Required surface grading over buried materials, if applicable. Existing natural flow patterns onto or from the construction site onto other properties must be a consideration in the final grading.
- i. Restrictions on the use of explosives, if any.
- j. Restrictions on the burning of combustible materials as a disposal procedure, if any.

- k. Special requirements for control of erosion, water pollution, and air pollution, if applicable. Requirements of this specification must be compatible with any and all requirements outlined in Construction Specification 5, [Pollution Control](#), when included as part of the contract.
- l. Method(s) of measurement and payment, if the standard specification includes more than one method.

4. DISCUSSION OF METHODS

a. Section 6, Measurement and Payment

- (1) Method 1 is intended for use when the area (s) to be cleared and grubbed is extensive and can be defined in units of area on the ground and on the drawings. Section 6 should specify horizontal or surface measurements to be used to determine area cleared and grubbed. A reservoir area is a typical example of this type of site.
- (2) Method 2 is intended for use when the area (s) to be cleared and grubbed is long and narrow. Section 6 should specify horizontal or surface measurements to be used to determine length of clearing and grubbing. A channel right-of-way is a typical example of this type of site.
- (3) Method 3 is intended for use when the area(s) to be cleared and grubbed is extensive, but the vegetation consists mainly of scattered trees, stumps, snags, etc., that can be measured individually.
- (4) Method 4 is intended for use when the area(s) to be cleared and grubbed cannot be measured practically and when it is reasonable to expect that variations in the estimated quantity of work to be performed will not occur after the contract is awarded. For Method 4, the procedures that will be used to determine the amount of work satisfactorily completed for progress payment needs to be identified in Section 7.

Options may include:

- an on site agreed-to estimate of the percent of work satisfactorily completed at time of cutoff; or
- require the contractor to provide measurements of all areas and identify those that have be satisfactorily cleared and grubbed, and use a percentage of the total bid item; or
- other suitable and fair methods, one of which could be related to construction schedule.

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

2. CLEARING AND GRUBBING

1. SCOPE

The work shall consist of clearing and grubbing and disposal of trees, snags, logs, brush, stumps, shrubs and rubbish from the designated areas.

2. PROTECTION OF EXISTING VEGETATION

Trees and other vegetation designated to remain undisturbed shall be protected from damage throughout the duration of the construction period. Any damages resulting from the Contractor's operations or neglect shall be repaired by the Contractor.

Earthfill, stockpiling of materials, vehicular parking, and excessive foot or vehicular traffic shall not be allowed within the drip line of vegetation designated to remain in place. Vegetation damaged by any of these or similar actions shall be replaced with viable vegetation of the same species, similar condition, and like size unless otherwise approved by the Contracting Officer.

Any cuts, skins, scrapes or bruises to the bark of the vegetation shall be carefully trimmed and local nursery accepted procedures utilized to seal damaged bark.

Any limbs or branches one-half (1/2) inch or greater in diameter which are broken, severed or otherwise seriously damaged during construction shall be cut off at the base of the damaged limb or branch flush with the adjacent limb or tree trunk.

All roots one (1) inch or greater in diameter which are cut, broken or otherwise severed during construction operations shall have the end smoothly cut perpendicular to the root. Roots exposed during excavation or other operations shall be covered with moist earth and/or backfilled as soon as possible to prevent the roots from drying out.

3. MARKING

The limits of the area(s) to be cleared and grubbed will be marked by means of stakes, flags, tree markings or other suitable methods. Trees to be left standing and uninjured will be designated by special markings placed on the trunk about six (6) feet above the ground surface.

4. CLEARING AND GRUBBING

All trees not marked for preservation and all snags, logs, brush, stumps, shrubs, rubbish and similar materials shall be cleared from within the limits of the designated areas. Unless otherwise specified, all stumps, roots and root clusters having a diameter of one (1) inch or larger shall be grubbed out to a depth of at least two (2) feet below subgrade for concrete structures and one (1) foot below the ground surface at embankment sites and other designated areas.

5. DISPOSAL

All materials cleared and grubbed from the designated areas shall be disposed of at locations shown on the drawings or in a manner specified in Section 7. The Contractor is responsible for complying with all local rules and regulations and the payment of any and all fees that may result from disposal at locations away from the project site.

6. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific units prices are established in the contract, the cleared and grubbed area will be measured to the nearest 0.1 acre. Payment for clearing and grubbing will be made for the total area within the designated limits at the contract unit price. Such payment will constitute full compensation for all labor, equipment, tools and all other items necessary and incidental to the completion of the work.

Method 2 For items of work for which specific unit prices are established in the contract, the length of the cleared and grubbed area will be measured to the nearest full station (100 feet) along the line designated on the drawing or identified in the specifications. Payment for clearing and grubbing will be made for the total length within the designated limits at the contract unit price. Such payment will constitute full compensation for all labor, equipment, tools and all other items necessary and incidental to the completion of the work.

Method 3 For items of work for which specific unit prices are established in the contract, each tree, stump and snag having a diameter of four (4) inches or greater and each log having a diameter of four (4) inches or greater and a length of ten (10) feet will be measured prior to removal. The size of each tree and snag will be determined by measuring its trunk at breast height above the natural ground surface. The size of each log will be determined by measuring the butt and by measuring its length from butt to tip. The size of each stump will be measured at the top. Diameter shall be determined by dividing the measured circumference by 3.14.

Payment for clearing and grubbing of each tree, stump and snag having a diameter of four (4) inches or greater and each log having a diameter of four (4) inches or greater and a length of ten (10) feet or greater will be made at the contract unit price for its size designation as determined by the following schedule:

Measured Diameter (in.)	Size Designation (in.)
4 to 8	6
8 to 12	10
12 to 24	18
24 to 36	30
36 to 60	48
Over 60	60

The sum of such payments shall constitute full compensation for clearing and grubbing; including the clearing and grubbing of smaller trees, stumps, snags, logs, brush, shrubs, roots, applicable permits and associated fees, and rubbish removal. Such payment shall constitute full compensation for all labor, equipment, tools and all other items necessary and incidental to the completion of the work.

Method 4 For items of work for which specific lump sum prices are established in the contract, payment for clearing and grubbing will be made at the contract lump sum price. Such payment shall constitute full compensation for all labor, equipment, tools and all other items necessary and incidental to the completion of the work.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 7.

STRUCTURE REMOVAL

1. APPLICABILITY

Construction Specification 3 is applicable to the removal of all types of structures, including fencing, from construction sites.

2. MATERIAL SPECIFICATIONS

There are no material specifications complementary to Construction Specification 3.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. The location and description of each structure or fence to be removed or the area from which structures are to be removed must be shown on the drawings. If structure removal is designated by area limits, the location and description of all buried structures to be removed must be shown together with area boundaries. All known information regarding the structure must be shown.
- b. The location and types of structures or fences to be preserved in place or to be salvaged must be shown on the drawings.
- c. The required extent and depth of removal.
- d. The locations of storage areas for salvaged structural materials must be shown on the drawings or indicated by appropriate notations. Note: A separate bid item may be required, due to cost sharing arrangements, when structure salvage is included in the contract.
- e. Areas where disposal of refuse material will not be permitted or areas where disposal will be limited, if known. If refuse materials must be disposed of outside the right-of-way or work limits, make appropriate notation.
- f. Structures, including fences, to be removed by others.
- g. Required minimum depth of earth cover, soil density requirements, and surface grading over buried materials, if applicable.
- h. Restrictions on the use of explosives, if any.
- i. Special requirements for control of erosion, water pollution, and air pollution, if applicable. Requirements of this specification must be compatible with any and all requirements outlined in Construction Specification 5, [Pollution Control](#), when included as part of the contract.
- j. Method(s) of measurement and payment, if the standard specification includes more than one method.

4. DISCUSSION OF METHODS

a. Section 2, Marking

- (1) Method 1 is intended for use when the structures to be removed are of significant size or when structures at several easy to identify locations must be removed. Whenever possible, this method is preferred over Method 2.
- (2) Method 2 may be used when several small structures located within the work limits are to be removed.

b. Section 3, Removal

- (1) Method 1 is compatible with Method 1, Marking, and must be used accordingly.
- (2) Method 2 is compatible with Method 2, Marking, and must be used accordingly.

c. Section 6, Measurement and Payment

- (1) Method 1 is for measurement and payment on a unit basis.
- (2) Method 2 is for payment on a lump sum basis. For this method, Section 7 should include the procedures that will be used to determine extent of satisfactory completed work for progress payment purposes.

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

3. STRUCTURE REMOVAL

1. SCOPE

The work shall consist of the removal, salvage, and disposal of structures (including fences) from the designated areas.

2. MARKING

Method 1 Each structure or structure part to be removed will be marked with stakes, flags, paint or other suitable method.

Method 2 The area boundaries from which structures must be removed will be marked by means of stakes, flags, paint or other suitable method. Structures to remain undisturbed or to be salvaged will be designated by special markings.

3. REMOVAL

Method 1 All structures designated for removal in the contract shall be removed to the specified extent and depth.

Method 2 Within the areas so marked, all visible and buried structures identified shall be removed to the specified extent and depth.

4. SALVAGE

Structures or structure parts that are designated to be salvaged shall be carefully removed and neatly placed in the specified or approved storage location. Salvaged structures that are capable of being disassembled shall be dismantled into individual members or sections. Such structures shall be neatly and systematically marked with paint prior to disassembly. All connectors and other parts shall be marked to indicate their proper location within the structure and shall be fastened to the appropriate structural member or packed in suitable containers.

Material from fences designated to be salvaged shall be placed outside the work area on the property on which the fence was originally located. Fence wire shall be rolled into uniform rolls of suitable size and neatly piled with other salvaged materials. Posts and rails shall be neatly stacked.

5. DISPOSAL OF REFUSE MATERIALS

Refuse materials resulting from structure removal shall be disposed of in a manner and at locations specified in Section 7 of this specification or in an acceptable manner and at locations approved by the Contracting Officer. Disposal by burning shall be in accordance with local rules and regulations.

6. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established by the contract, payment for the removal of each structure unit, except fences, will be made at the contract unit price. Fences removed or removed and salvaged will be measured to the nearest linear foot. Payment for fence removal or removal and salvage will be made at the contract unit prices for each type and size of fence.

Such payment will constitute full compensation for all labor, equipment, tools, applicable permits and associated fees for burning and disposal of refuse, and all other items necessary and incidental to the completion of the work.

Method 2 For items of work for which specific lump sum prices are established by the contract, payment for structure removal will be made at the contract lump sum price.

Such payment will constitute full compensation for all labor, equipment, tools, applicable permits and associated fees for burning and disposal of refuse, and all other items necessary and incidental to the completion of the work.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract, but not listed as a contract line item number in the bid schedule, will be included in the payment for the item of work to which it is made subsidiary. Such items and items to which they are made subsidiary are identified in Section 7 of this specification.

CHANNEL CLEARING AND SHAPING

1. APPLICABILITY

Construction Specification 4 is applicable to the clearing, removal, and disposal of woody and other vegetation; removal and disposal of trash and rubbish; and the earth shaping of the bottom and sides of the channel. This specification is applicable for natural floodways, constructed channels, and other drainage systems.

2. MATERIAL SPECIFICATIONS

There are no material specifications complementary to Construction Specification 4.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. The special markings indicating trees to be left standing, undisturbed, and uninjured must be described.
- b. For Section 2, Protection of Existing Vegetation, when the specific size of replacement plant is known or is desired, specify the number, size and species of the replacement in Section 8. Example: "Any tree designated to remain or is irreparably damaged shall be replaced with two 15 gallon size Valley Oak (*Quercus lobata*) as directed by the Contracting Officer."
- c. Areas in which disposal of refuse material or other waste materials resulting from channel clearing and shaping activities will not be allowed or areas where disposal will be limited or restricted, if known.
- d. Restrictions on the burning of combustible materials as a disposal procedure, if any.
- e. The reaches of the stream or channel where shaping is to be performed.
- f. An illustration and/or description that provides the shaping requirements.
- g. Method(s) of measurement and payment, if the standard specification includes more than one method.

4. DISCUSSION OF METHODS

a. Section 7, Measurement and Payment

- (1) Method 1 is intended for irregular-shaped reaches that need to be physically measured in the field. Section 8 should specify horizontal or surface measurements to be used to determine area cleared and shaped.
- (2) Methods 2 and 3 are intended for long channel reaches with uniform widths and minor variations in width, respectively. Section 8 should specify

horizontal or surface measurements to be used to determine area cleared and shaped.

(3) Method 4 is intended for use where the amount of work required is relatively consistent throughout the described work area. For this method, procedures that will be used to determine the amount of work satisfactorily completed for progress payment needs to be identified in Section 8. Options may include:

- an on site agreed-to estimate of the percent of work satisfactorily completed at time of cutoff;
or
- require the contractor to provide supporting calculations to determine extent of work satisfactorily completed;
or
- other suitable and fair methods, one of which could be related to the construction schedule.

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

4. CHANNEL CLEARING AND SHAPING

1. SCOPE

The work shall consist of clearing designated areas by the removal and disposal of trees, logs, stumps, shrubs, brush, and rubbish, and the shaping of the channel.

2. PROTECTION OF EXISTING VEGETATION

Trees and other vegetation designated to remain undisturbed shall be protected from damage throughout the duration of the construction period. Any damages resulting from the Contractor's operations or neglect shall be repaired by the Contractor.

Earthfill, stockpiling of materials, vehicle or equipment parking, and excessive foot or vehicle traffic shall not be allowed within the drip line of vegetation designated to remain in place. Vegetation damaged by any of these or similar actions shall be replaced with viable vegetation of the same species, similar condition, and like size unless otherwise approved by the Contracting Officer.

Any cuts, skins, scrapes or bruises to the bark of the vegetation shall be carefully trimmed and local nursery accepted procedures utilized to seal damaged bark.

Any limbs or branches one-half (1/2) inch or greater in diameter which are broken, severed or otherwise seriously damaged during construction shall be cutoff at the base of the damaged limb or branch, flush with the adjacent limb or tree trunk.

All roots one (1) inch or greater in diameter which are cut, broken or otherwise severed during channel shaping shall have the end smoothly cut perpendicular to the root. Roots exposed during channel shaping operations shall be covered with moist soil as soon as possible to prevent roots from drying out.

3. MARKING

The limits of the area(s) to be cleared and shaped will be marked by means of stakes, flags, paint, tree markings or other suitable methods, or as specified in Section 8 of this specification, or will be shown on the drawings. Trees to remain standing, undisturbed, and uninjured will be designated by special markings.

4. CLEARING

Trees and other vegetation marked for clearing shall be cut off as near the ground surface as conventional tools and equipment will normally permit. All trees not marked for preservation and all snags, logs, brush, shrubs, stumps, and rubbish shall be cleared from within the area limits identified.

5. DISPOSAL

All woody material, vegetation, and rubbish resulting from clearing from designated areas shall be disposed of at the locations and in a manner shown on the drawings, or as specified in Section 8 of this specification.

6. SHAPING

The channel bottom and side slopes shall be shaped as shown on the drawings. The resulting shaped channel surface shall be reasonably smooth. Material excavated during the channel shaping operation shall be removed from the channel and disposed of as specified in Section 8 of this specification.

7. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established by the contract, the designated cleared and shaped area will be measured and the area determined to the nearest 0.1 acre. Payment for clearing and shaping will be at the contract unit price for the item and shall constitute full compensation for all labor, equipment, tools, applicable permits and associated fees for burning and disposal of refuse, and all other items necessary and incidental to the satisfactory completion of the work.

Method 2 For items of work for which specific unit prices are established by the contract, the length of the cleared and shaped channel designated will be measured to the nearest 100 feet. Payment for clearing and shaping will be made at the contract unit price for the item and shall constitute full compensation for all labor, equipment, tools, applicable permits and associated fees for burning and disposal of refuse, and all other items necessary and incidental to the satisfactory performance of the work.

Method 3 For items of work for which specific unit prices are established by the contract, the cleared and shaped area(s) will be measured and the area determined to the nearest 0.1 acre. The designated cleared and shaped area(s) will be determined from the measured width at representative sections and the distance between the sections. Payment for clearing and shaping will be made at the contract unit price for the item and shall constitute full compensation for all labor, equipment, tools, applicable permits and associated fees for burning and disposal of refuse, and all other items necessary and incidental to the satisfactory completion of the work.

Method 4 For items of work for which specific lump sum prices are established by the contract, the extent of clearing and shaping will not be measured or determined for payment. Payment for clearing and shaping will be made at the contract lump sum price for the item and shall constitute full compensation for all labor, equipment, tools, applicable permits and associated fees for burning and disposal of refuse, and all other items necessary and incidental to the satisfactory completion of the work.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract, but not listed in the bid schedule, will be included in the payment for the item of work to which it is made subsidiary. Such items and items to which they have been made subsidiary are identified in Section 8 of this specification.

POLLUTION CONTROL

1. APPLICABILITY

This specification is applicable to the control or reduction of pollution from all construction activities.

2. MATERIAL SPECIFICATIONS

There are no material specifications complementary to this specification. Any material specifications required shall be specified in Section 8 of this specification.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. The area to be controlled should be defined and the limits to be treated shall be shown on the drawings and/or described in the construction specifications.
- b. If areas to be treated are not easily definable on the site map, such as some channel projects, the extent of treatment shall be fully described by notes or designated by stations or right-of-way limits.
- c. Restrictions or special requirements limiting the selection of best management practices for control or treatment should be specified.
- d. Special requirements designating the sequence of construction operations. These requirements might require temporary or prolonged shutdown periods of some or all construction operations.
- e. Alternate methods of control, if applicable.
- f. Any restrictions on amount of area disturbed before treatment is started.
- g. Any restriction on timing of installation, operation, or remove any of the controls or treatments. Stabilization and structural practices such as; diversions, stream crossings, sediment basins, sediment filters, and waterways are typically specified as temporary and to be removed. If any of these practices are to remain in place, specify in Section 8, along with any maintenance or changes required before final acceptance.
- h. Special pollution control requirements, such as sectional excavation or placement of materials, burying operations, waste area reclamation, blasting, clearing, dredging, or other unique construction procedure or operation.
- i. Water and chemicals for dust control is covered in Section 5. Payment for water for dust control may be included as an item of work under this specification or Construction Specification [10, Water for Construction](#). The intent is to be covered in Section 8 of this specification.

- j. Any other special requirements pertaining to this specification, including reference to applicable state and local laws and regulations.
- k. Storm Water Pollution Prevention Plan (SWPPP) requirements. Environmental Protection Agency or State requirements shall be followed as applicable.
- l. Method of measurement and payment.

4. CONSTRUCTION METHODS TO BE APPLIED IN CONTRACTS TO CONTROL POLLUTION

The following list does not include all possible erosion and pollution control methods. All personnel concerned with planning, design, and construction should study the site carefully and specify needed practices required to control erosion, sediment, and air pollution. Pollution control specifications are to be coordinated with the SWPPP requirements developed to meet the National Pollution Discharge Elimination System (NPDES) program.

a. Structures

- (1) Limit clearing and grubbing prior to actual need. Protect vegetation where possible.
- (2) Install terraces, diversions, or level spreaders, including stable outlets.
 - (a) Above and below borrow areas.
 - (b) Above earth emergency spillways.
 - (c) Above storage areas.
- (3) Control access and haul roads.
 - (a) Contour roads and grade surfaces away from slopes and toward controlled outlets.
 - (b) Dust control with water and/or chemicals.
 - (c) Erosion control by installing turnouts, culverts, and stabilize road ditches.
 - (d) Vegetate disturbed areas.
 - (e) Surface roughening or pitting.
- (4) Shape and control borrow areas. Reduce area and duration of exposed areas.
- (5) Install debris basins, brush dams, straw bale barriers and geotextile fences.
- (6) Locate, shape, size and protect by-pass channel.
 - (a) Use coffer dams.
 - (b) Pump extra water across construction area.

- (7) Sectional construction.
- (8) Timely installation of all structural and stabilization practices.
- (9) Control work sequence.
- (10) Complete as you go.
- (11) Winter or seasonal shut downs to minimize pollution control problems.
- (12) Good housekeeping practices, to prevent water or air pollution, in use at the work site at all times.
- (13) Seeding for temporary and/or permanent protection. Provide topsoil as appropriate.
- (14) Prevent wild fires. Burn only per regulations.
- (15) Prevent pollution by chemicals and lubricants.
- (16) Mulch unprotected areas.

b. Channels

- (1) Preserve natural vegetation where possible. Remove blocks if possible.
- (2) Leave old channel to function as long as possible. Perform new channel excavation as an initial construction activity.
- (3) Where possible, do not open new channel to flows until vegetation is established. Sequence work.
- (4) Seed or sod slopes immediately after construction. Provide topsoil as necessary.
- (5) Mulch or mat slopes immediately after disturbance.
- (6) Spray mulch, seed, fertilizer, and asphalt or polyvinyl resin, etc.
- (7) Begin excavation downstream and work upstream.
- (8) Use temporary grade control structures.
- (9) Limit clearing, clearing and grubbing, and snagging.
- (10) Limit disturbance of channel banks to one side. Delay and complete other side after the initial side is vegetated.

- (11) Channel construction should be performed in segments, completing each segment prior to starting the next segment.
- (12) Control storm water inlets into channel.
- (13) Install pipe inlets, grade control structures, etc., at the time of construction.
- (14) Install sediment traps in channel and provide for their clean out and maintenance.

5. DISCUSSION OF METHODS

a. Section 7, Measurement and Payment

- (1) Method 1 This method provides measurement and payment by the unit of work performed. The use of water and chemical suppressants inappropriately and excessive to need may be clarified in Section 8.
- (2) Method 2 This method provides for payment on the lump sum basis with progress payments determined from invoices provided by the Contractor.
- (3) Method 3 This method provides for payment on the lump sum basis with measurement on a prorated and equal basis for each monthly payment period.

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

5. POLLUTION CONTROL

1. SCOPE

The work shall consist of installing measures or performing work to control erosion and minimize the production of sediment and other pollutants to water and air from construction activities.

2. MATERIALS

All materials furnished shall meet the requirements of the Material Specifications listed in Section 8 of this specification.

3. EROSION AND SEDIMENT CONTROL MEASURES AND WORKS

The measures and works shall include, but are not limited to, the following:

Staging of Earthwork Activities The excavation and moving of soil materials shall be scheduled to minimize the size of areas disturbed and unprotected from erosion for the shortest reasonable time.

Seeding Seeding to protect disturbed areas shall occur as soon as reasonably possible following completion of that earthwork activity.

Mulching Mulching to provide temporary protection of soil surfaces from erosion.

Diversions Diversions to divert water from work areas and to collect water from work areas for treatment and safe disposition. These works are temporary and shall be removed and the area restored to its near original condition when they are no longer required or when permanent measures are installed.

Stream Crossings Culverts or bridges where equipment must cross streams. These works are temporary and shall be removed and the restored to its near original condition when they are no longer required or when permanent measures are installed.

Sediment Basins Sediment basins to collect, settle and eliminate sediment from eroding areas from impacting properties and streams below the construction site(s). These works are temporary and shall be removed and the area restored to its original condition when they are no longer required or when permanent measures are installed.

Sediment Filters Straw bale filters or geotextile sediment fences to trap sediment from areas of limited runoff. Sediment filters shall be properly anchored to prevent erosion under or around them. These works are temporary and shall be removed and the area restored to its original condition when they are no longer required or when permanent measures are installed.

Waterways Waterways for the safe disposal of runoff from fields, diversions and other structures or measures. These works are temporary and shall be removed and the area restored to its original condition when they are no longer required or when permanent measures are installed.

Other Additional protection measures as specified in Section 8 of this specification or required by Federal, State, or Local Government.

4. CHEMICAL POLLUTION

The Contractor shall provide water-tight tanks or barrels, or construct a sump sealed with plastic sheets to be used to dispose of chemical pollutants, such as drained lubricating or transmission fluids, grease, soaps, concrete mixer wash water, asphalt, etc., produced as a by-product of the construction activities. At the completion of the construction work, sumps shall be removed and the area restored to its original condition as specified in Section 8 of this specification. Sump removal shall be conducted without causing pollution.

Sanitary facilities such as chemical toilets, or septic tanks shall not be located adjacent to live streams, wells, or springs. They shall be located at a distance sufficient to prevent contamination of any water source. At the completion of construction activities, facilities shall be disposed of without causing pollution as specified in Section 8 of this specification.

5. AIR POLLUTION

The burning of brush and/or slash, and disposal of other materials shall adhere to state and local regulations.

Fire prevention measures shall be taken to prevent the start or spreading of wild fires which may result from project activities. Firebreaks or guards shall be constructed and maintained at locations shown on the drawings.

All public access or haul roads used by the contractor during construction of the project shall be sprinkled or otherwise treated to fully suppress dust. All dust control methods shall insure safe construction operations at all times. If chemical dust suppressants are applied, the material shall be a commercially available product specifically designed for dust suppression and the application shall follow manufacturer's requirements and recommendations. A copy of the product data sheet and manufacturer's recommended application procedures shall be provided to the Engineer five (5) working days prior to the first application.

6. MAINTENANCE, REMOVAL, AND RESTORATION

All pollution control measures and temporary works shall be adequately maintained in a functional condition for the duration of the construction period. All temporary measures shall be removed and the site restored to near original condition.

7. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established in the contract, each item will be measured to the nearest unit applicable. Payment for each item will be made at the contract unit price for that item. For water or chemical suppressant items used for dust control for which items of work are established in Section 8 of this specification, measurement for payment will not include water or chemical suppressants that are used inappropriately or excessive to need. Such payment will constitute full compensation for the completion of the work.

Method 2 For items of work for which lump sum prices are established in the contract, payment will be made as the work proceeds and supported by invoices presented by the Contractor that reflect actual costs. If the total of all progress payments is less than the lump sum contract price for this item, the balance remaining for this item will be included in the final contract payment. Payment of the lump sum contract price will constitute full compensation for completion of the work.

Method 3 For items of work for which lump sum prices are established in the contract, payment will be prorated and provided in equal amounts on each monthly progress payment estimate. The number of months used for prorating shall be the number estimated to complete the work as outlined in the Contractor's approved construction schedule. The final month's prorate amount will be provided with the final contract payment. Payment as described above will constitute full compensation for completion of the work.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items, and the items to which they are made subsidiary, are identified in Section 8 of this specification.

INSTRUCTIONS FOR USE OF CONSTRUCTION SPECIFICATION 6

SEEDING, SPRIGGING AND MULCHING

1. APPLICABILITY

Construction Specification 6 is applicable to vegetating and/or mulching all designated areas requiring protective cover following completion of construction operations.

2. MATERIAL SPECIFICATIONS

Material requirements are included in this specification.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Complete plans of the designated areas to be treated, including locations of disposal sites for oversize rocks and other debris.
- b. Name of plant or mixture to include scientific name, common name, and acceptable cultivars.
- c. Purity, germination, hard seed, and weed seed requirements for seed or mixture. Certified (e.g. Blue Tag) seed may be specified.
- d. Fertilizer, lime and other soil amendment requirements, if applicable.
- e. Inoculant requirements, if needed.
- f. Types of mulch, straw, hay, native hay, etc., and mulching methods, when required.
- g. Dates for seeding, sprigging, fertilizing, and mulching operations.
- h. Rates for seeding, sprigging, fertilizing, and mulching operations, expressed in pounds pure live seed (PLS) per acre.
- i. Method of application of seed, sprigs, fertilizer, and mulch.
- j. Method of anchoring mesh or netting.
- k. Supplemental irrigation to support vegetation establishment; frequency, volume per application, duration, etc. It is critical with some soils that over irrigation and soil saturation be avoided.

4. DISCUSSION OF METHODS

a. Section 6, Measurement and Payment

(1) Method 1 Measurements used to determine the size of the area treated should specify horizontal or surface measured values in Section 7.

Constructed fill and/or cut slopes steeper than three (3) feet horizontal to one

- (1) foot vertical should consider surface measurements to calculate areas for payment purposes.
- (2) Methods 2 and 3 The procedures that will be used to determine the amount of work satisfactorily completed for progress payment should be identified in Section 7.

Options may include:

- an on-site agreed-to estimate of the percent of work satisfactorily complete at time of progress payment preparation; or
- require the contractor to provide invoices (Method 3) to support his incurred costs to satisfactory complete work at time of progress payment; or
- other suitable and fair methods, one of which could be related to the construction schedule.

When specifications are prepared electronically and all but one method are deleted for use in a contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

6. SEEDING, SPRIGGING AND MULCHING

1. SCOPE

The work shall consist of preparing the area for treatment, furnishing and placing seed, sprigs, mulch, fertilizer, inoculant, lime and other soil amendments, and anchoring mulch in designated areas as specified.

2. MATERIALS

Seed - All seed shall conform to the current rules and regulations of the state where it is being used and shall be from the latest crop available. It shall meet or exceed the standard for purity and germination listed in Section 7.

Seed shall be labeled in accordance with the state laws and the U.S. Department of Agriculture Rules and Regulations under the Federal Seed Act in effect on the date of invitations for bids. Bag tag figures will be evidence of purity and germination. No seed will be accepted with a test date of more than nine (9) months prior to the delivery date to the site.

Seed that has become wet, moldy, or otherwise damaged in transit or storage will not be accepted. The percent of noxious weed seed allowable shall be as defined in the current state laws relating to agricultural seeds. Each type of seed shall be delivered in separate sealed containers and fully tagged unless exception is granted in writing by the Engineer.

Fertilizer - Unless otherwise specified, the fertilizer shall be a commercial grade fertilizer. The fertilizer shall meet the standard for grade and quality specified by state law. Where fertilizer is furnished from bulk storage, the Contractor shall furnish a supplier's certification of analysis and weight. When required by the contract, a representative sample of the fertilizer shall be furnished to the Engineer for chemical analysis.

Inoculants - The inoculant for treating legume seeds shall be a pure culture of nitrogen-fixing bacteria prepared specifically for the species and shall not be used later than the date indicated on the container or as otherwise specified. A mixing medium, as recommended by the manufacturer, shall be used to bond the inoculant to the seed. Two times the amount of the inoculant recommended by the manufacturer shall be used, except four times the amount shall be used when seed is applied by use of a hydraulic seeder. Seed shall be sown within twenty-four (24) hours of treatment and shall not remain in the hydraulic seeder longer than four (4) hours.

Lime and other Soil Amendments - Lime shall consist of Standard Ground Agriculture Limestone, or approved equivalent. Standard Ground Agriculture Limestone is defined as ground limestone meeting current requirements of the State Department of Agriculture. Other soil amendments shall meet quality criteria and application requirements specified in Section 7.

Mulch Tackifiers - Asphalt emulsion tackifiers shall conform to the requirements of ASTM D 977, Specification for Emulsified Asphalt. The emulsified asphalt may be rapid setting, medium setting, or slow setting. Non-asphaltic tackifiers required because of environmental considerations shall be as specified in Section 7.

Straw Mulch Materials - Straw mulch shall consist of wheat, barley, oat or rye straw, hay, grass cut from native grasses or other plants as specified in Section 7. The mulch material shall be air dry, reasonably light in color, and shall not be musty, moldy, caked, or otherwise of low quality. The use of mulch that contains noxious weeds will not be permitted. The Contractor shall provide a method satisfactory to the Engineer for determining weight of mulch furnished.

Other Mulch Materials - Mulching materials, such as wood cellulose fiber mulch, mulch tackifiers, synthetic fiber mulch, netting, and mesh are other mulching materials that may be required for specialized locations and conditions. These materials, when specified, must be accompanied by the manufacturer's recommendations for methods of application.

3. SEEDING MIXTURES, SOD, SPRIGS AND DATES OF PLANTING

The application rate per acre for seed mixtures, sprigs, or sod and date of seeding or planting shall be as shown on the plans or as specified in Section 7.

4. SEEDBED PREPARATION AND TREATMENT

Areas to be treated shall be dressed to a smooth, firm surface. On sites where equipment can operate on slopes safely, the seedbed shall be adequately loosened (4 to 6 inches deep) and smoothed. Depending on soil and moisture conditions, disking or cultipacking or both may be necessary to properly prepare a seedbed. On sites where equipment cannot operate safely, the seedbed shall be prepared by hand methods by scarifying to provide a roughened soil surface so that broadcast seed will remain in place.

If seeding is to be accomplished immediately following construction operations, seedbed preparation may not be required except on compacted, polished, or on freshly cut soil surfaces.

Rocks larger than six (6) inches in diameter, trash, weeds, and other debris that will interfere with seeding or maintenance operations shall be removed or disposed of as specified in Section 7.

Seedbed preparation shall be discontinued when soil moisture conditions are not suitable for the preparation of a satisfactory seedbed as determined by the Engineer.

5. SEEDING, SPRIGGING, FERTILIZING, MULCHING, AND STABILIZING

All seeding or sprigging operations shall be performed in such a manner that the seed and/or sprigs are applied in the specified quantities uniformly on the

designated areas. The method and rate of seed application shall be as specified in Section 7. Unless otherwise specified, seeding or sprigging shall be accomplished within two (2) days after final grading is completed and approved.

Fertilizer, lime, and other soil amendments shall be applied as specified in Section 7. When specified, the fertilizer and soil amendments shall be thoroughly incorporated into the soil immediately following surface application.

The rate, amount, and kind of mulching or mesh shall be as specified in Section 7. Mulches shall be applied uniformly to the designated areas, and shall be applied to areas seeded not later than two (2) working days after seeding has been performed. Straw mulch material shall be stabilized within twenty-four (24) hours of application by the use of a mulch crimper or equivalent anchoring tool or by a suitable tackifier. When the mulch crimper or equivalent anchoring tool is used, it shall have straight blades and be the type manufactured expressly for, and capable of firmly punching the mulch into the soil. On sites where the equipment can be safely operated, it shall be operated on the contour. On sites where equipment cannot safely operate to perform the work required, hand methods shall be used.

The tackifier shall be applied uniformly over the mulch material at the specified rate, or by injecting it into the mulch material as it is being applied. The mesh or netting stabilizing materials shall be applied smoothly but loosely on the designated areas, and the edges shall be buried or securely anchored by means of spikes or staples as specified in Section 7.

The Contractor shall maintain the mesh or netting areas until all work under the contract has been completed and accepted. Maintenance shall consist of the repair of areas damaged by water erosion, wind, fire, or other causes. Such areas shall be repaired to re-establish the intended condition and to the design lines and grades required by the contract. The areas shall be re-fertilized, re-seeded, and re-mulched prior to the new application of the mesh or netting.

6. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established in the contract, each area treated will be measured as specified in Section 7 and the area calculated to the nearest 0.1 acre. Payment for treatment will be made at the contract unit price for the designated treatment which will constitute full compensation for completion of the work.

When specified as an item of work, mesh or netting will be measured to the nearest square yard of surface area covered and accepted. Payment will be made at the contract unit price and will constitute full compensation for completion of the work.

Method 2 For items of work for which specific lump sum prices are established in the contract, the quantity of work will not be measured for payment. Payment for this item will be made at the contract lump sum price for the item and will constitute full compensation for the completion of the work.

Method 3 For items of work for which lump sum prices are established in the contract, payment will be made as the work proceeds. Progress payments will be determined as specified in Section 7. Payment of the lump sum contract price will constitute full compensation for completion of the work.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the item(s) to which they are made subsidiary are identified in Section 7.

CONSTRUCTION SURVEYS

1. **APPLICABILITY**

Construction Specification 7 is applicable to construction contracts containing clauses requiring the Contractor to provide construction surveys, layout and measurement from government established baselines and bench marks; to provide quantity surveys, measurements and computations for progress payment estimates; and when Method 3, Section 5, is authorized, provide original and final surveys for final quantity determinations.

2. **MATERIAL SPECIFICATIONS**

There are no material specifications complementary to this specification. Any material requirements are to be specified in Section 9.

3. **ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS**

- a. Baselines, benchmarks, and all other basic survey control information to be provided by the government are to be indicated on the drawings.
- b. Number of copies, format and timing of the submittal of survey data, notes, computations, etc., to be provided to the Engineer by the Contractor.
- c. Special requirements for advance notification of surveys to be performed by the Contractor.
- d. Quality of any material, as applicable. Example may be the providing of permanent reference stakes.
- e. Qualifications of construction survey personnel such as qualified construction personnel, certified or licensed land surveyors, or registered engineers. Provide a list outlining the minimum requirements expected.
- f. Special requirements for staking, such as offset reference stakes and hubs for excavations and fills.
- g. Requirements other than the standards of the industry such as being consistent with NRCS procedures or higher levels of accuracy than those specified. Precision and accuracy is discussed in EFH Chapter 1.
- h. Any special surveys, etc., to be performed by either the Contractor or the government, that are not listed in Section 5.

4. DISCUSSION OF METHODS

a. Section 5, Construction Surveys

- (1) Method 1 is for use where the government provides basic staking that includes alignment, grade and slope stakes. Other staking shall be performed by the Contractor and is considered quality control construction staking and surveys for the determination of work accomplished for progress payment purposes.
- (2) Method 2 is for use where the Contractor performs all surveys required for the layout and control of construction work and all surveys necessary for progress payment quantities. This does not include original (initial) and final surveys for determining final quantities for payment purposes.
- (3) Method 3 is the same as Method 2 except the Contractor is required to perform the original (initial) and final surveys for use in determining final payment quantities. Note: The use of Method 3 requires approval to use FAR Clause 52.236-16, Quantity Surveys, Alternate I. NRCS policy for Field Surveys is located in NEM Section 540.04, Contractor Surveys; Section 540.05, Checking; and, Section 540.06, Responsibility. The project's Quality Assurance Plan should outline the checking requirements. The State Conservation Engineer has the authority to approve construction documents (drawings and specifications) that outline the survey responsibilities. Administrative authority to use Method 3 rests with the Contract Specialist on the Regional Office Staff.

b. Section 8, Payment

- (1) Method 1 is for use when a related construction survey activity is significant and not expected to be uniform throughout the contract.
- (2) Method 2 is for use when the extent of required construction survey is minor and could be expected to be fairly uniform throughout the duration of the contract.

When specifications are prepared using electronic procedures and all but one method are deleted for use in a contract specification, delete "All Methods The following provisions apply to all methods of payment." and left justify the remaining text.

Note: The implementation of methods within this construction specification needs to be compatible with the Quality Assurance Plan prepared and approved for the project.

CONSTRUCTION SPECIFICATION

7. CONSTRUCTION SURVEYS

1. SCOPE

The work shall consist of performing all surveys, measurements and computations required by this specification.

2. EQUIPMENT AND MATERIAL

Equipment for construction surveys shall be of a quality and condition to provide the required accuracy. The equipment shall be maintained in good working order and in proper adjustment at all times. Records of repairs, calibration tests, accuracy checks and adjustments shall be maintained and be available for inspection by the Engineer. Equipment shall be checked, tested, and adjusted as necessary in conformance with manufacturer's recommendations.

Material includes all the necessary field notebooks, stakes, templates, platforms, equipment, spikes, steel pins, tools, and all other items necessary to perform the work specified.

3. QUALITY OF WORK

All work shall follow recognized professional practice and the standards of the industry unless otherwise specified in Section 9 of this specification. The work shall be performed to the accuracy and detail appropriate for the type of job. Notes, sketches, and other data shall be complete, recorded neatly, legible, reproducible and organized in a manner that facilitates ease in review and will allow reproduction of copies for job documentation. Survey equipment that requires little or no manual recording of field data shall have survey information documented as outlined in Section 9 of this specification.

All computations shall be mathematically correct and shall include information to identify the bid item, date, and who performed, checked and approved the computations. Computations shall be legible, complete and clearly document the source of all information used including assumptions and measurements collected.

If a computer program is used to perform the computations, the Contractor shall provide the Engineer with the software identification, vendor's name, version number, and other pertinent data, prior to beginning survey activities. Computer generated computations shall show all input data including values assigned and assumptions made.

The elevations of permanent and temporary benchmarks shall be determined and recorded to the nearest 0.01 foot. Differential leveling and transit traverses shall be of such precision that the error of vertical closure in feet shall not exceed plus or minus 0.1 times the square root of the traverse distance in miles. Linear measurements shall be accurate to within 1.0 foot in 5000 feet, unless otherwise specified in Section 9 of this specification. The angular error of closure for transit

traverses shall not exceed 1.0 minute times the square root of the number of angles turned.

The minimum requirements for placing slope stakes shall be at 100 foot stations for tangents, as little as 25-feet for sharp curves, breaks in the original ground surface and at any other intermediate stations necessary to insure accurate location for construction layout and measurement. Slope stakes and cross sections shall be perpendicular to the centerline. Significant breaks in grade shall be determined for cross sections. Distances shall be measured horizontally and recorded to the nearest 0.1 foot. Side shots for interim construction stakes may be taken with a hand level.

Unless otherwise specified in Section 9 of this specification, measurements for stationing and establishing the location of structures shall be made to the nearest 0.1 foot.

Elevations for concrete work, pipes and mechanical equipment shall be determined and recorded to the nearest 0.01 foot. Elevations for earthwork shall be determined and recorded to the nearest 0.1 foot.

4. PRIMARY CONTROL

The baselines and bench marks for primary control, necessary to establish lines and grades needed for construction, are shown on the drawings and have been located on the job site.

These baselines and benchmarks shall be used as the origin of all surveys, layouts and measurements to establish construction lines and grades. The Contractor shall take all necessary precautions to prevent the loss or damage of primary control points. Any stakes and/or control points lost or damaged by construction activity will be re-established by the Contractor or at Contractor expense.

5. CONSTRUCTION SURVEYS

Prior to commencement of work requiring contractor performed surveys, the Contractor shall submit in writing for Engineer's review: the name, qualifications and experience of the individual's to be assigned to the survey tasks.

Method 1 Contractor performed surveys shall include: (1) checking and any supplemental or interim staking, (2) performing quantity surveys, measurements and computations for progress payment, (3) other surveys as described in Section 9 of this specification.

Method 2 Contractor performed surveys shall consist of all work necessary for: (1) establishing line and grade for all work, (2) setting slope stakes for all work, (3) checking and any supplemental or interim staking, (4) establishing final grade stakes, (5) performing quantity surveys, measurements and computations for

progress payment and (6) other surveys as described in Section 9 of this specification.

Method 3 Contractor performed surveys shall consist of all work necessary for: (1) establishing line and grade for all work, (2) setting slope stakes for all work, (3) checking and any supplemental or interim staking, (4) establishing final grade stakes, (5) performing quantity surveys, measurements and computations for progress payments, (6) performing original (initial) and final surveys for determinations of final quantities, and (7) other surveys as described in Section 9 of this specification.

6. STAKING

Prior to the commencement of work on any item, the construction staking required for the item shall be completed. Construction staking shall be completed as follows, or as otherwise specified in Section 9 of this specification:

- a. Clearing and grubbing - The boundary of the area(s) to be cleared and grubbed shall be staked or flagged at a maximum interval of 200 feet, closer if needed, to clearly mark the limits of work. When Contractor staking is the basis for determining the area for final payment, all boundary stakes will be reviewed by the Engineer prior to start of this work item.
- b. Excavation and fill - Slope stakes shall be placed at the intersection of the specified slopes and ground line. Slope stakes and the reference stakes for slopes shall be marked with the stationing, required cut or fill, slope ratio and horizontal distance from the centerline or other control line. The minimum requirements for placing slope stakes is outlined in Section 3, Quality of Work.
- c. Structures - Centerline and offset reference line stakes for location, alignment and elevation shall be placed for all structures.

7. RECORDS

All survey data shall be recorded in fully identified standard hardbound engineering survey field notebooks with consecutively numbered pages. All field notes and printed data shall include the purpose or description of the work, the date the work was performed, weather data, sketches and the personnel who performed and checked the work. Electronically generated survey data and computations shall be bound, page numbered and cross-referenced in a bound field notebook containing the index for all survey activities. All work shall follow recognized professional practice.

The construction survey records shall be available at all times during the progress of the work for examination and use by the Engineer and when requested, copies shall be made available. The original field notebooks and other records shall be provided to and become the property of the owner prior to final payment and acceptance of all work.

Complete documentation of computations and supporting data for progress payments shall be submitted to the Engineer with each invoice for payment as specified in Section 9 of the specification. When the Contractor is required to conduct initial and final surveys as outlined in Section 5, CONSTRUCTION SURVEYS, notes shall be provided as soon as possible after completion to the Engineer for the purpose of determining final payment quantities.

8. PAYMENT

Method 1 For items of work for which lump sum prices are established in the contract, payment will be made as the work proceeds, after presentation of correct and accurate invoices by the Contractor showing related costs and evidence of the charges of suppliers, subcontractors, and others for supplies furnished and work performed. Invoices for the total amount of the contract price will not be accepted until all surveys are complete and required documentation has been determined complete. If the total of such payments is less than the lump sum contract price for this item, the unpaid balance will be included in the final contract payment. Payment of the lump sum contract price will constitute full compensation for completion of all work under the bid item.

Method 2 For items of work for which lump sum prices are established in the contract, payment will be made as the work proceeds with progress payment amounts determined as a percentage of the total work planned as projected from the Contractor's approved construction schedule. Payment of the lump sum contract price will constitute full compensation for completion of all work under this bid item.

Payment will not be provided under this item for the purchase price of materials and/or equipment having a residual value.

All Methods The following provisions apply to all methods of payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the item to which they are made subsidiary are identified in Section 9 of this specification.

MOBILIZATION AND DEMOBILIZATION

1. APPLICABILITY

Construction Specification 8 is applicable to any construction contract that includes a bid item for general mobilization and demobilization of the Contractor's personnel and equipment. It is not intended to cover mobilization and demobilization of special equipment for specific items of work, such as grouting equipment, pile driving equipment, rock drilling equipment, etc., for which payment for mobilization and demobilization is included and provided by specific bid items elsewhere in the contract.

2. MATERIAL SPECIFICATION

There are no material specifications complementary to Construction Specification 8.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Special requirements pertaining to mobilization and demobilization, if any.
- b. Any particular work for which payment will or will not be made under the mobilization and demobilization item if not adequately described by the specification.
- c. When more than one site(s) (work limits not continuous) are included in the contract, include in Section 4 of this specification if mobilization of contractor's equipment and personnel between sites are included or not included in Section 3, Payment.

4. DISCUSSION OF METHODS

No Methods are outlined in the Specification.

CONSTRUCTION SPECIFICATION

8. MOBILIZATION AND DEMOBILIZATION

1. SCOPE

The work shall consist of the mobilization and demobilization of the Contractor's forces and equipment necessary for performing the work required under the contract.

This work shall not include mobilization and demobilization for specific items of work for which payment is provided elsewhere in the contract.

Mobilization will not be considered as work in fulfilling the contract requirements for commencement of work.

2. EQUIPMENT AND MATERIALS

Mobilization shall include all activities and associated costs for transportation of Contractor's personnel, equipment, and operating supplies to the site; establishment of offices, buildings, and other necessary general facilities for the Contractor's operations at the site; premiums paid for performance and payment bonds, including coinsurance and reinsurance agreements as applicable; and other items specified in Section 4 of this specification.

Demobilization shall include all activities and costs for transportation of personnel, equipment, and supplies not required or included in the contract from the site; including the disassembly, removal and site clean up, of offices, buildings and other facilities assembled on the site specifically for this contract.

This work includes mobilization and demobilization required by the contract at the time of award. If additional mobilization and demobilization activities and costs are required during the performance of the contract as a result of changed, deleted, or added items of work for which the Contractor is entitled to an adjustment in contract price, compensation for such costs will be included in the price adjustment for the item or items of work changed or added.

3. PAYMENT

Payment will be made as the work proceeds, after presentation of paid invoices and/or documentation of direct costs by the Contractor showing specific mobilization and demobilization costs and supporting evidence of the charges of suppliers, subcontractors, and others. When the total of such payments is less than the lump sum contract price, the balance remaining will be included in the final contract payment. Payment of the lump sum contract price for mobilization and demobilization will constitute full compensation for completion of the work.

Payment will not be made under this item for the purchase costs of materials having a residual value, the purchase costs of materials to be incorporated in the project, or the purchase costs of operating supplies.

INSTRUCTIONS FOR USE OF CONSTRUCTION SPECIFICATION 9

TRAFFIC CONTROL

1. APPLICABILITY

This specification is applicable to providing facilities for control of traffic and providing public safety during construction.

2. MATERIAL SPECIFICATIONS

There are no material specifications complementary to Construction Specification 9.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Any local constraints in traffic control, utilities, and access of local residents to their homes shall be stated.
- b. Provide information on any required permits and/or approvals.
 - (1) List any traffic control permits required and the issuing agency.
 - (2) List any fees and/or inspection costs that may be required as a result of obtaining a permit.
- c. Any special local activities that would generate above average vehicle use by the public. Outline the dates that this activity could occur so construction schedules would be considerate of this potential conflict. Examples: State and County Fairs, rodeos, sporting events, special local holiday or seasonal activities, etc.
- d. Name(s) and contact information for local authorities responsible for traffic control, maintenance, and public safety in the project area.
- e. The appropriate state or other acceptable technical reference(s) shall be identified. Also, provide for issuing agency's name, contact person, address, telephone number, and ordering information, as appropriate.

Example:

Manual of Traffic Controls for Construction and Maintenance of Work Zones

(Reference)

State of California; Business, Transportation and Housing Agency, Department of Transportation

(Issued by)

(Contact Person's Name and Title)

(805) 792-4729 CDOT-39-2870
(Telephone No.) (Order No.)

- f. For Measurement and Payment, outline the procedures that will be used to determine the percent of work completed for progress payments if it differs from that outlined in Section 6.

4. DISCUSSION OF METHODS

No Methods are outlined in the Specification.

CONSTRUCTION SPECIFICATION

9. TRAFFIC CONTROL

1. SCOPE

The work shall consist of establishing traffic control and maintaining safe, convenient use of public roads and rights-of-way.

2. TRAFFIC AND ACCESS

The Contractor's operations shall cause no unnecessary inconvenience to the public. The public rights-of-way shall be maintained at all times unless interruption is authorized by proper local authority. Contractor's authorized closing and/or detour plans shall be provided the Engineer for approval.

Safe and adequate access shall be provided and maintained to all public protection devices and to all critical utility control locations. Facility access shall be continuous and unobstructed unless otherwise approved.

3. STORAGE OF EQUIPMENT AND MATERIALS IN PUBLIC STREETS

Construction materials and equipment shall not be stored or parked on public streets, roads, or highways. During any material or equipment loading and/or unloading activities that may temporarily interfere with traffic, acceptable detour(s) shall be provided for the duration of the activity. Any associated expense for this activity will be the responsibility of the Contractor.

Excavated material, including suitable material that is intended for adjacent trench backfills or other earth backfill as specified in Section 5 of this specification, shall not be stored in public streets, roads, or highways that remain in service for the public. Any waiver of this requirement must be obtained from the proper local authority and approved by the Engineer. All excess and unsuitable material shall be removed from the site as soon as possible. Any spillage shall be removed from roadways prior to use by the public.

4. STREET CLOSURES, DETOURS, AND BARRICADES

The Contractor shall comply with the requirements of all applicable responsible units of government for closure of any street, road, or highway. The Contractor shall provide the required barriers, guards, lights, signs, temporary bridges, and flaggers together with informing the public of any detours and construction hazards by the most suitable means available such as local newspapers, local radio stations, etc. The Contractor shall also be responsible for compliance with additional public safety requirements that may arise during construction. The Contractor shall furnish and install, and upon completion of the work, promptly remove all signs, warning devices, and other materials used in the performance of this work.

Unless otherwise specified, not less than seven (7) days prior to closing, or partially closing, or reopening any street, road, or highway, the Contractor shall notify, in

writing, the Fire Chief, Police Chief, County Sheriff, State Patrol, schools that operate school buses, or any other government official as may be appropriate.

Unless otherwise specified, the Contractor shall furnish to the Engineer a written plan showing the proposed method of signing, barricading for traffic control, and safety for street detours and closures.

All temporary detours will be maintained to ensure use of public rights-of-way is provided in a safe manner. This may include dust control, grading, graveling, etc. as required in Section 7 of this specification.

5. GENERAL AND SPECIFIC REFERENCES

All signs, signals, barricades, use of flaggers, and other traffic control and public safety devices shall conform to the general requirements set forth in the "Manual of Uniform Traffic Control Devices" (MUTCD) and the latest edition of "Standard Highway Signs and Standard Alphabets for Highway Signs" and/or OSHA Construction Industry Standards (29 CFR Part 1926), Subpart G, Signs, Signals, and Barricades unless otherwise specified in Section 7 of this specification.

6. MEASUREMENT AND PAYMENT

For items of work for which specific lump sum prices are established in the contract, payment for the work will be made at the contract lump sum price. Progress payments will be made based upon the percentage of estimated total time that traffic control will be required unless otherwise specified in Section 7 of this specification. Payment will constitute full compensation for all flaggers, labor, materials, equipment and all other items necessary and incidental to completion of the work.

Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and items to which they are made subsidiary are identified in Section 7 of this specification.

WATER FOR CONSTRUCTION

1. APPLICABILITY

Construction Specification 10 is applicable to all water required at the construction site except for water used for mixing and/or curing grout and concrete covered by Construction Specifications 14, 31, 32, 33, 35, 62, and 63. Construction Specification 10 is to be made a part of the contract when a pay item for water is provided. More than one pay item and method of payment may be used if the source of water is expected to be different, the volume of water required is uncertain, and the cost is expected to vary.

2. MATERIAL SPECIFICATIONS

There are no Material Specifications complementary to Construction Specification 10.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Pay item for water in units of 1,000 gallons with an estimated quantity provided.
- b. Designated source of water with details of ownership and water rights, if applicable.
- c. Cost to the Contractor of water at the designated source, if applicable. Note: It may be advantageous for NRCS or Sponsor to contract separately with the owner of the water and furnish it to the Contractor free at the source. This should be considered only if the net cost to the NRCS or Sponsors would be less than if included in the bid by the Contractor.
- d. Special requirements pertaining to furnishing and using water, including water quality requirements if quality may be a problem for the purpose intended.
- e. Details on metering, accuracy, gauge certification, location of meter for payment purposes, or other requirements imposed by state and/or local agencies for measuring water use. Specify in Section 8 of this specification where meters are located if there is a concern for water losses between the measured source and the point of delivery or application. A statement such as "Meters shall be installed at the point of delivery into the water hauling equipment or application systems; such as, sprinkler systems, flooding systems, etc." may be used.
- f. Details of the costs and expenses that will be included in the pay items if exceptions are to be made in the measurement and payment option selected from Section 7.

4. DISCUSSION OF METHODS

a. Section 7, Measurement and Payment

- (1) Method 1 must be used when the cost of water is paid but the remaining costs of transporting water, distributing it for construction purposes, and application are subsidiary to the items of work they are associated. Only costs of water at the meter will be paid for under this method.
- (2) Method 2 must be used when the cost of water and all other associated transportation, distribution and application costs are included in the unit cost of water.
- (3) Method 3 must be used when the water is provided to the Contractor without cost and the remaining costs of transportation, distribution and application are to be paid at the unit price for each 1,000 gallons applied.

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

10. WATER FOR CONSTRUCTION

1. SCOPE

The work shall consist of furnishing, transporting, measuring, and applying water as specified.

2. FACILITIES AND EQUIPMENT

The Contractor shall install and maintain access and haul roads and furnish, operate, and maintain all pumps, meters, piping, tanks, storage and other facilities required to load, transport, store, distribute, and use construction water as specified.

These facilities shall be equipped with accurate, work dedicated meters, tanks of known volume, or other devices that will provide a correct measurement of water supplied. Meters shall be installed at the point of delivery into water hauling equipment or application system; such as, sprinkler systems, flooding systems, etc., as specified.

3. DUST ABATEMENT AND HAUL ROAD MAINTENANCE

Water for dust abatement and haul road maintenance shall be applied to haul roads and other dust producing areas as needed to prevent air pollution or excessive dust, which causes impaired vision on trafficked roads and in work areas, and to maintain the roads in good condition for safe and efficient operation during periods of use. Roads that may be jointly used with the public and by the Contractor's equipment, shall have dust abatement provisions acceptable to the public entity that has road maintenance responsibility. Compensation for water used for dust abatement and haul road maintenance shall be as specified in Section 8 of this specification.

4. EARTHFILL, DRAINFILL, AND ROCKFILL

Water required for proper installation of earthfill, drainfill, and/or rockfill shall be utilized in the fill materials as specified in the applicable construction specifications. Compensation for construction water used for earthfill, drainfill and/or rockfill shall be as specified in Section 8 of this specification.

5. CONCRETE, MORTAR, AND GROUT

Water required in the mixing or curing of concrete, shotcrete, roller compacted concrete, or other portland cement mortar or grout shall meet the requirements of the applicable construction specifications and shall be used in conformance with those specifications. Payment for construction water used in these items is covered by the applicable concrete, mortar, and/or grout specifications.

6. OTHER CONSTRUCTION REQUIRING WATER

Water required and used for other construction activities under this contract but not specifically covered by this specification shall be considered subsidiary to the item(s) of work which requires its use.

7. MEASUREMENT AND PAYMENT

Method 1 For water items for which specific unit prices are established in the contract, the volume of water furnished and utilized in accordance with the specifications will be measured to the nearest 1,000 gallons.

Payment for water will be made at the contract unit price. Such payment will constitute full compensation for the direct costs of water. All other costs necessary for applying water are subsidiary to the items of work they are associated.

Method 2 For water items for which specific unit prices are established in the contract, the volume of water furnished and utilized in accordance with the specifications will be measured to the nearest 1,000 gallons.

Payment for water and the cost associated with transportation, distribution and application will be made at the contract unit price. Such payment will constitute full compensation for completion of the work.

Method 3 For water items for which specific unit prices are established in the contract, the volume of water utilized in accordance with the specifications will be measured to the nearest 1,000 gallons.

Payment for water will be made at the contract unit price. Such payment, excluding water cost, will constitute full compensation for completion of the work.

All Methods The following provisions apply to all methods of measurement and payment:

- a. The measurement for payment will include all water utilized, except as noted in Sections 5, 6, and 8 of this specification. Measurement for payment will not include water that is utilized inappropriately or excessive to need.
- b. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 8 of this specification.

REMOVAL OF WATER

1. **APPLICABILITY**

Construction Specification 11 is applicable to the temporary diversion of surface water and dewatering of the borrow and construction areas during the construction period.

2. **MATERIAL SPECIFICATIONS**

There are no material specifications complementary to Construction Specification 11.

3. **ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS**

- a. Special requirements or restrictions for the diversion system and/or method of diverting surface water.
- b. Special requirements for dewatering the construction site that may affect quality of work and/or construction safety (such as lowering water table prior to performing excavations and maintaining a maximum water level during construction operations).
- c. Special requirements for dewatering borrow areas such as removal of surface water and subsurface drainage to contribute to proper soil moisture conditions during borrow excavation operations. A contract bid item should be included if water problems may be expected in the borrow area and additional work, such as installation and operation of a pumping system, could be expected.
- d. Information on alternate borrow sources that may not require dewatering.
- e. Special requirements for the control of erosion and water pollution. Requirements included in this specification should be directly associated with dewatering and be compatible with Construction Specification 5, [Pollution Control](#), if also used as a contract bid item.
- f. Waiver of the requirement that the Contractor furnish a site-specific plan outlining procedures to divert surface water and dewatering the construction site, if a plan in writing is not necessary.
- g. Depending on the magnitude and complexity expected, diverting surface water and dewatering may require separate bid items.
- h. For Section 6, Removal of Temporary Works, if pollution of the ground water is a concern when clean gravel is used as backfill, specify other backfill procedures in Section 8.
- i. Provisions for payment, if payment is to be made on a unit price basis, for pumping to dewater borrow areas and construction sites as follows:

- (1) Contract bid item for pumping to dewater borrow areas or construction sites.
- (2) At least one lump sum contract bid item that will include compensation for the work and cost of preparation for pumping.

4. DISCUSSION OF METHODS

a. Section 7, Measurement and Payment

- (1) Method 1 is intended when removal of water is to be covered by one or more lump sum contract bid items. The procedures that will be used to determine progress payments should be outlined in Section 8.
- (2) Method 2 is intended for use when pumping to dewater borrow areas is to be measured and paid for as a unit price bid item of work.

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

11. REMOVAL OF WATER

1. SCOPE

The work shall consist of the removal of surface water and ground water as necessary to perform the construction required by the contract in accordance with the specifications. It shall include: (1) constructing, installing, building, and maintaining all necessary temporary water containment facilities, channels, and diversions, (2) furnishing, installing, and operating all necessary pumps, piping, and other facilities and equipment, and (3) removing all such temporary works and equipment after their intended function is no longer required.

2. DIVERTING SURFACE WATER

The Contractor shall install, maintain and operate all cofferdams, channels, flumes, sumps, and all other temporary diversion and protective works needed to divert stream flow and other surface water through or around the construction site. Control of surface water shall be continuous during the period that damage to construction work could occur. Unless otherwise specified and/or approved, the diversion outlet shall be into the same drainage way that the water would have reached before being diverted.

The Contractor shall furnish the Engineer in writing, a proposed plan for diverting surface water before beginning any construction activities for which a diversion is required, unless waived in Section 8 of this specification. Acceptance of this plan, or the waiving of the plan requirement, will not relieve the Contractor of the responsibilities related to this activity during the process of completing the work as specified.

3. DEWATERING THE CONSTRUCTION SITE

Foundations, cutoff trenches, and all other parts of the construction site shall be dewatered and kept free of standing water and muddy conditions as necessary for the proper execution of the work. The Contractor shall furnish, install, operate, and maintain all drains, sumps, pumps, casings, well points, and all other equipment required to properly dewater the site as specified. Dewatering systems that cause a loss of soil fines from the foundation areas will not be permitted.

4. DEWATERING BORROW AREAS

The Contractor shall maintain all borrow areas free of surface water and otherwise provide for timely and effective removal of surface and subsurface water that accumulates within the borrow area, unless waived in Section 8 of this specification. Borrow material shall be processed as necessary to achieve proper and uniform moisture content at the time of placement.

If pumping to dewater borrow areas is included as a bid item of work in the bid schedule, each pump discharge pipe shall be equipped with a water meter. Meters shall be such that the measured quantity of water is accurate within three (3) percent

of the true quantity. The Contractor shall provide necessary support to perform accuracy tests of the water meters when requested by the Engineer.

5. EROSION AND POLLUTION CONTROL

Removal of water from the construction site, including the borrow areas, shall be accomplished in a manner that erosion and the transporting of sediment and other pollutants are minimized. Dewatering activities shall be accomplished in a manner that the water table water quality is not altered. Pollution control activities shall not conflict with the requirements of Construction Specification 5, [Pollution Control](#), if it is a part of this contract.

6. REMOVAL OF TEMPORARY WORKS

When temporary works are no longer needed, the Contractor shall remove and return the area to a similar condition that existed prior to construction. Areas where temporary works were located shall be graded for slightly appearance with no obstruction to natural surface water flows or the proper functioning and access to the works of improvement installed. The Contractor shall exercise extreme care during the removal stages to minimize the loss of soil sediments and debris that was trapped during construction.

Pipes, casings, and any other material used to dewater the site shall be removed from temporary wells. The wells shall be filled to ground level with clean gravel or other suitable material approved by the Engineer unless specified otherwise in Section 8 of this specification. The Contractor shall exercise extreme care to prevent pollution of the ground water by these actions.

7. MEASUREMENT AND PAYMENT

Method 1 Items of work listed in the bid schedule for removal of water, diverting surface water, and dewatering construction sites and borrow areas will be paid for at the contract lump sum prices. Such payment will constitute full compensation for all labor, equipment, tools and all other items necessary and incidental to the completion of the work.

Method 2 Items of work listed in the bid schedule for removal of water, diverting surface water, dewatering construction sites, and dewatering borrow areas will be paid for at the contract lump sum prices. Such payment will constitute full compensation for furnishing, installing, operating, and maintaining the necessary trenches, drains, sumps, pumps, and piping, and for all labor, equipment, tools, and all other items necessary and incidental to the completion of the work, except that additional payment for pumping to dewater borrow areas and the removal of water will be made as described in the following paragraph.

If pumping to dewater borrow areas is a contract bid item, payment will be made at the contract unit price which shall be the price per 1,000 gallons shown in the bid schedule. Such payment will constitute full compensation for pumping only.

Compensation for equipment and preparation and for other costs associated with pumping will be included in the lump sum payment for removal of water or the lump sum payment for dewatering the borrow areas. Payment will be made only for pumping that is necessary to dewater borrow areas that cannot be effectively drained by gravity or that must have the water table lowered to be usable as a suitable borrow source. Pumping for other purposes will not be included for payment under this item.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract, but not listed in the bid schedule, will be included in the payment for the contract line item to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 8 of this specification.

RELIEF WELLS

1. APPLICABILITY

Construction Specification 12 is applicable to the construction of pressure relief wells in foundations of structures.

2. MATERIAL SPECIFICATION

Material Specification [521, Aggregates for Drainfill and Filters](#), and [554, Steel Pipe](#), are complementary to Construction Specification 12.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Plan location of each well.
- b. Profile along the line of wells showing the spacing and estimated depths of the wells.
- c. Sectional elevation of typical wells showing:
 - (1) The location of the well screens, if required;
 - (2) The diameter and vertical extent of the filter;
 - (3) Details of the outlet at the upper end of the filter;
 - (4) Details of couplings and special fittings and appurtenances such as tees, check valves, caps and appurtenant housings.
- d. Special limits on time of installation. For example, it may be required that the relief wells be installed before any structural load is placed on the foundation or prior to a specific phase of construction.
- e. The type and size of pipe.
- f. The type and size of well screens including the size and pattern of screen openings or slots.
- g. The grading requirements of the filter material.
- h. Section 7, note in Section 13 when well development is required.
- i. Acceptable methods of plugging abandoned wells in Section 13. Requirements placed on the Contractor must be in conformance with state and local regulations for this activity.

4. DISCUSSION OF METHODS

Two methods are included in Section 11, Measurement, and three methods in Section 12, Payment. These methods are self-explanatory, but it must be noted that Methods 1 and 2 of Section 11 are, respectively, complementary to Methods 1 and 2 of Section 12.

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

12. RELIEF WELLS

1. SCOPE

The work shall consist of installing and developing pressure relief wells in foundations of earth structures.

2. MATERIALS

The well screen shall be of the specified type and size, and the size and pattern of the screen openings shall conform to the details shown on the drawings. Each screen shall be equipped with a bottom plug of the same material as the screen.

The riser pipe and fittings shall conform to the requirements of Material Specification [547](#), [551](#), and [554](#) for the type of pipe specified in Section 13 of this specification. Filter materials shall conform to the requirements of Material Specification [521](#) and shall be graded as specified in Section 13 of this specification.

3. LOCATION AND DEPTH OF WELLS

The plan location and depth of each well shown on the drawings are based on design estimates. The final depth and location of the components of each well will be determined by the Engineer on the basis of the examination of the well log and samples recovered during drilling. The location of a well will be changed by the Engineer where obstructions encountered during drilling require abandonment of the proposed well location.

4. DRILLING

Unless otherwise specified, the wells shall be drilled vertically by a rotary drilling procedure. The diameter of each well shall be adequate to permit the placement of the specified thickness of filter material. As determined by the Engineer, drilling methods that may reduce the yield of the well will not be permitted.

The well shall be cased with a temporary casing of a type that:

- a. Shall have sufficient thickness to retain its shape and maintain the true section throughout its total depth; and
- b. Shall be removable in a manner that will not disturb the filter, well screen or riser pipe.

5. INSTALLING RISER PIPE AND SCREEN

The riser, consisting of the riser pipe, well screens, couplings and fittings, shall be measured and inspected as it is assembled and placed in the well. Spiders, or other centering devices, shall be attached to the assembled riser in sufficient numbers to center it within the well and to accurately maintain its position during the placement of the filter material.

Before the riser is placed, filter materials shall be placed at the bottom of the well to the elevation specified by the Engineer for the bottom of the well screen. The riser shall be placed in the well in such a manner as to avoid shock and to prevent damage to any of its components. The relief outlet or top of the riser shall be securely maintained at the designated elevation during the placement of the filter material.

6. PLACING FILTER/DRAINFILL

The filter material shall be placed by tremie, or other method approved by the Engineer, to an elevation not less than one (1) foot above the top of the highest well screen. At the initial placement operations, the tremie shall rest on the bottom of the well and be filled with filter material. The tremie and the temporary casing shall be raised in increments of not more than two (2) feet allowing the filter material to flow from the bottom of the tremie. The top surface of the filter material in the tremie shall be maintained above the water surface at all times. The top surface of the filter material in the well shall be maintained a minimum of two (2) feet above the bottom of the casing as the casing is raised.

7. DEVELOPING

Following filter material placement and when specified in Section 13 of this specification, the well shall be developed by an approved method. Prior to development, the Contractor shall submit a plan for accomplishing the work to the Engineer for review.

All materials pulled into the screen during development shall be removed. Filter material shall be added to the annular space around the screen as needed to maintain the top of the filter at the specified elevation.

Any well that continues to produce appreciable amounts of fines after development for a period of four hours will be abandoned and relocated unless otherwise continued by the Engineer.

8. BACKFILLING

After the well has been developed, the annular space around the riser pipe above the filter material shall be filled with selected moist impervious earthfill or portland cement concrete. Backfill shall be placed in layers not to exceed twelve (12) inches in thickness and each layer shall be tamped firmly into place. The temporary casing shall be withdrawn in increments as the backfill is placed.

9. ABANDONED WELLS

All abandoned wells shall be plugged as specified in Section 13 of this specification. When a well is abandoned after development, the well screen and riser pipe shall be salvaged, whenever possible.

10. LOGGING AND SAMPLING

The Contractor shall conduct drilling operations in such a manner that the Engineer may take representative disturbed soil samples of all materials encountered.

11. MEASUREMENT

Method 1 The amount of well drilling will be measured to the nearest foot of well drilled and cased. Wells abandoned for causes other than the fault of the Contractor will be included in the measurement for payment.

The volume of filter material and backfill material will be computed to the nearest 0.1 cubic yard from measurements of the vertical well space occupied by each and the outside diameters of the casing and riser. Filter material and backfill material for wells abandoned for causes not attributed to actions of the Contractor will be included in the measurement for payment.

The amounts of pipe and well screen installed in the riser and outlet assembly will be measured to the nearest linear foot at the time the riser is assembled. Pipe and well screen that cannot be salvaged from wells abandoned for causes not attributed to actions of the Contractor will be included in the measurement for payment.

The number of couplings and special fittings and appurtenances will be counted at the time the riser is assembled. Couplings and special fittings and appurtenances that cannot be salvaged from wells abandoned for causes not attributed to actions of the Contractor will be included in the measurement for payment.

The time required to develop each well will be measured to the nearest one-half hour. Time required to develop wells abandoned for causes not attributed to actions of the Contractor will be included in the measurement for payment.

Method 2 The amount of well drilling will be measured to the nearest foot of well drilled and cased. Wells abandoned for causes not attributed to actions of the Contractor will be included in the measurement for payment.

The volume of each grading of filter material placed will be computed to the nearest 0.1 cubic yard from measurements of the vertical well space occupied by each and the diameters of the casing and riser. Filter in wells abandoned for causes not attributed to actions of the Contractor will be included in the measurement for payment.

The amounts of pipe, couplings, fittings, appurtenances and well screen installed in the riser and outlet assembly will be measured to the nearest linear foot at the time the riser is assembled.

Pipe, couplings, fittings, appurtenances and well screen that cannot be salvaged from wells abandoned for causes not attributed to actions of the Contractor will be included in the measurement for payment.

The time required to develop each well will be measured to the nearest one-half hour. Time required to develop wells abandoned for causes not attributed to actions of the Contractor will be included in the measurement for payment.

Backfill will not be measured.

12. PAYMENT

Method 1 Payment for each item of work will constitute full compensation for all labor, equipment, materials and all other items necessary and incidental to the completion of the work included in the item.

Payment for drilling and casing each size of well will be made at the contract unit price for that size of well and will include compensation for drilling, casing, and pulling casing.

Payment for furnishing and placing filter material will be made at the contract unit price for that grading of filter material.

Payment for furnishing, placing and compacting backfill will be made at the contract unit price.

Payment for furnishing and installing each type and size of pipe will be made at the contract unit price for that type and size of pipe.

Payment for furnishing and installing each type and size of well screen will be made at the contract unit price for that type and size of well screen.

Payment for furnishing and installing each coupling will be made at the contract unit price for that type and size of coupling.

Payment for each special fitting or appurtenance will be made at the contract unit price for that type and size of fitting or appurtenance.

Payment for developing each well will be made at the contract unit price for developing that size of well.

Method 2 Payment for each item of work will constitute full compensation for all labor, equipment, materials and all other items necessary and incidental to the completion of the work included in the item.

Payment for drilling, casing and backfilling each size of well will be made at the contract unit price for that size of well and will include compensation for drilling, casing, pulling casing, and backfilling.

Payment for furnishing and placing filter material will be made at the contract unit price for that grading of filter material.

Payment for furnishing and installing each type and size of pipe complete with all couplings, fitting and appurtenances (except well screens) will be made at the contract unit price for that type and size of pipe.

Payment for furnishing and installing each type and size of well screen will be made at the contract unit price for that type and size of well screen.

Payment for developing each well will be made at the contract unit price for developing that size of well.

Method 3 Measurement will not be made. Items of work listed in the bid schedule for installing, operating, and removal of relief wells will be paid for at the contract lump sum prices. Such payment will constitute full compensation for all labor, equipment, tools and all other items necessary and incidental to the completion of the work.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 13 of this specification.

PILING

1. APPLICABILITY

Construction Specification 13 is applicable to the furnishing and installation of timber piles, steel piles, steel sheet piles, pre-cast concrete piles, and shells for cast-in-place piles. It is not applicable to the installation of drilled, cast-in-place piles.

2. MATERIAL SPECIFICATIONS

Material Specifications [511 \(Steel Piles\)](#), [512 \(Wood Piles\)](#), [513 \(Precast Concrete Piles\)](#), and [514 \(Cast-in-Place Concrete Piles\)](#) are complementary to Construction Specification 13. Include Construction Specification [31, Concrete for Major Structures](#), or [32, Structure Concrete](#), as appropriate, when not included in the contract for other concrete installation.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Plan showing the location of all piles, including test piles, if any.
- b. Foundation profiles and sections showing:
 - (1) Log of borings, including penetration test results;
 - (2) Required or estimated pile penetration;
 - (3) Cutoff elevations.
- c. Required bearing capacities. (Note: Specify (1) required bearing capacity or (2) required penetration or (3) required bearing capacity and minimum penetration, as appropriate.)
- d. For timber piles state the type, class, species and length of piles required. For Type I piles, state where the piles will be inspected. For Type II piles, state the type of treatment and minimum retention of preservative per cubic foot of pile.
- e. Details of pre-cast or cast-in-place concrete piles including dimensions, reinforcement details, class of concrete, size of aggregate, type of cement and slump required.
- f. Nominal size and weight of Section for H-bearing piles.
- g. Authorization to use gravity drop hammers, if appropriate.
- h. Details of load tests that will be required, if appropriate.
- i. Methods of measurement and payment if the standard specification includes more than one method.

4. DISCUSSION OF METHODS

a. Section 12, Measurement and Payment

- (1) Methods 1 and 2 are intended for use when a considerable number of piles of about the same length are required. Method 1 provides for a single pay item for furnishing and driving piles. Method 2 provides for separate pay items for furnishing piles and driving piles.
- (2) Method 3 may be used when the lengths of piles required may be quite variable. It is particularly suitable where the cutoff portions of the piles may be salvaged and used on the job, such as when steel bearing piles are specified.
- (3) Method 4 may be used for sheet pile walls when the required depth of penetration is known.

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

13. PILING

1. SCOPE

The work shall consist of furnishing and installing the specified kinds and types of piles at the locations shown on the drawings.

2. MATERIALS

Piles shall conform to the requirements of Material Specifications 511, 512, 513, or 514 as appropriate to the kinds of piles specified. For piles of material other than that list above, the material requirements outlined in Section 14 of this specification shall apply.

3. SITE PREPARATION

All excavation within the area to be occupied by bearing piles shall be completed before the piles are driven.

4. PROTECTION OF PILE HEADS

The heads of all piles shall be protected during driving by suitable caps, rings, heads, blocks, mandrels and other devices.

The heads of timber piles shall be fitted into a steel head block or fitted with heavy steel or wrought iron rings or wire wrapping.

The heads of steel piles shall be cut square and fitted with a steel driving cap.

The heads of pre-cast concrete piles and casings shall be fitted into cushion type drive caps having a rope or other suitable cushion next to the pile head and fitting into a casting which in turn supports a timber shock block.

Driving heads, mandrels and other devices shall be provided by the Contractor as needed for special types of piles and shall conform to the recommendations of the pile manufacturer.

5. PILES, GENERAL

The Contractor shall notify the Engineer before pile driving operation commences. Such notice shall be far enough in advance, a minimum of 24 hours, to provide the Engineer adequate time to be present for the driving operations. Piles shall be driven only in the presence of the Engineer or authorized representative.

The determination of piling order lengths shall be the Contractor's responsibility, unless otherwise specified.

Unless otherwise approved, piles shall be driven with steam, air, diesel powered hammers or a combination of hammers, vibration or water jets. Water jets may be

used only when specifically authorized by the Engineer. Where jetting is authorized, the jets shall be withdrawn before the specified depth or bearing capacity is obtained and the piles shall be driven with the hammer to the final penetration.

When drop hammers are permitted, the height of drop shall not be more than eight (8) feet for concrete piles or twelve (12) feet for steel and timber piles, unless otherwise specified.

The driving of piling with followers shall be allowed only when expressly approved by the Engineer.

Piles shall not be driven within 20 feet of concrete less than seven (7) days after placement, including concrete placed in cast-in-place piles with or without pre-driven shells or casings.

The Contractor shall not attempt to drive piles beyond the point of refusal, as indicated by excessive bouncing of the hammer or kicking of the pile.

6. BEARING PILES

Bearing piles shall be driven to the position, line, and batter specified on the drawings. Each pile shall be driven continuously and without interruption to the specified depth or until the specified bearing capacity is obtained. Deviation from this procedure will be permitted only when interruption of driving is caused by conditions that could not reasonably be anticipated.

When a diesel hammer is used, it shall be operated at full throttle when blows are counted for determination of bearing capacity except that throttle adjustments shall be made as necessary to prevent the non-striking parts of the hammer from rising from the pile on the ram upstroke.

7. SHEET PILES

The piling shall be driven in such a manner as to insure perfect interlocking throughout the entire length of each pile. The piles shall be held in proper alignment during driving by means of assembling frames or other suitable temporary guide structures. Temporary guide structures shall be removed when they have served their purpose.

At any time that the forward edge of the sheet pile wall is found to be out of correct alignment:

- a. The piling already assembled and partly driven shall be driven to the required depth.
- b. Taper piles shall then be driven to bring the forward edge into correct alignment before additional regular piling is assembled and driven. The maximum permissible taper in a single pile shall be one-fourth inch per foot of length.

8. ESTIMATING BEARING CAPACITY

When load tests are not required, the bearing capacity of each pile shall be estimated by use of one of the following formulas, as appropriate:

a. For gravity hammers, $R = \frac{2WH}{S+1}$

- b. For single-acting steam or air hammers and for diesel hammers having unrestricted rebound of the ram,

$$R = \frac{2WH}{S+0.1}$$

- c. For double-acting steam or air hammers and diesel hammers having enclosed rams,

$$R = \frac{2H(W+AP)}{S+0.1} ; \quad \text{or, } R = \frac{2E}{S+0.1}$$

where:

- R = safe bearing capacity in pounds,
W = weight, in pounds, of striking parts of hammer,
H = height of fall in feet,
A = area of piston in square inches,
P = pressure, in pounds per square inch, of steam, air or other gas exerted on the hammer piston or ram,
E = the manufacturer's rating for foot-pounds of energy developed by double-acting steam or air hammers, or 90 percent of the average equivalent energy, in foot-pounds, developed by diesel hammers having enclosed rams as evaluated by gauge and chart readings,
S = average penetration, inches per blow, for the last five (5) to ten (10) blows of a gravity hammer or the last ten (10) to twenty (20) blows for steam, air or diesel powered hammers.

The above formulas are applicable when:

- The hammer has a free fall
- The head of the pile is not crushed
- The penetration is reasonably quick and uniform
- There is no sensible bounce after the blow
- A follower is not used.

Twice the height of the bounce shall be deducted from "H" to determine its value in the formula.

In case water jets are used in conjunction with the driving, the bearing power shall be determined by the above formulas from the results of driving after the jets have been removed.

9. LOAD TESTS

When load tests are specified, the test loads shall be applied gradually, without impact, and in a manner that no lateral forces are applied to the pile. Load testing shall not be started until twenty-four (24) hours after driving of the test pile is completed unless otherwise specified in Section 14 of this specification. Except as otherwise specified, load tests shall be performed according to the following procedures:

The total test load shall be twice the specified working load and shall be applied to the pile in increments equal to 25-percent of the working load. Settlement of the top of the pile shall be measured to an accuracy of 0.01-inch before and after the application of each load increment and at 2, 4, 8, 15, 30, and 60 minutes after, and then every two (2) hours until the next load increment is applied. Additional load shall not be applied until the rate of settlement is less than 0.01-inch in one (1) hour.

The total test load shall remain on the pile for a minimum period of twenty-four (24) hours. Settlement shall be measured at six (6) hour intervals during this period and at the end of the period, at least twice during removal of the load, and immediately after all of the test load is removed. The net settlement shall be measured approximately twenty-four (24) hours after the total load has been removed.

If settlement continues in excess of 0.01-inch per hour under less than the total test load, no additional load shall be applied, but the load that has been applied shall remain on the pile a minimum of twenty-four (24) hours, and settlement measurements while the load is on the pile, and during and after removal of the load shall be made as if it were the total test load.

10. CUTTING OFF PILES

The Contractor shall cut the piles at the specified elevations. The length of pile cut off shall be sufficient to permit the removal of all damaged material. Steel shells or concrete casings for cast-in-place concrete piles shall be cut off at the specified elevation before being filled with concrete.

Steel bearing piles shall be cut off in clean, straight lines as shown on the drawings. Any irregularities shall be leveled off with deposits of weld metal or by grinding before placement of bearing caps.

Pre-cast concrete piles and concrete casings shall be cut off in a manner such as to prevent damage to the remaining portion of the pile or casing or to the projecting reinforcement required for connecting the piles to the structure.

Timber piles that are to be capped shall be accurately cut off so that true bearing is obtained on every pile without the use of shims.

11. DEFECTIVE PILES

Any pile damaged in driving, driven out of proper location, driven below the specified cut off elevation or inaccurately cut off shall be corrected by one of the following methods, whichever is approved by the Engineer:

- a. The defective pile shall be pulled and replaced or re-driven;
- b. A new pile shall be driven adjacent to the defective pile; or
- c. The defective pile shall be spliced or built up or a sufficient portion of the footing shall be extended to properly embed the pile.

Pile shells abandoned in place after driving shall be filled with concrete or sand-cement grout as appropriate to the conditions that are present.

All piles pushed up by the driving of adjacent piles or by any other cause shall be re-driven to final grade.

Any sheet pile ruptured in the interlock or otherwise damaged during driving shall be pulled and replaced.

12. CORRECTING SURFACE HEAVE

Any excess material resulting from displacement of earth by pile driving shall be removed. Materials disturbed by pile driving shall be conditioned and compacted to a minimum density equal to adjacent undisturbed material.

13. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established in the contract, the number of each type, kind, and length of pile driven in place will be counted. Payment for furnishing and driving each type, kind, and length of pile will be made at the contract unit price. Such payment will constitute full compensation for all labor, equipment, materials, and all other items necessary and incidental to the completion of the work.

Method 2 For items of work for which specific unit prices are established in the contract, the number of each type, kind, and length of pile furnished, accepted, and stockpiled in good condition at the site of the work will be counted. Payment for furnishing each type, kind, and length of pile will be made at the contract unit price. Payment for driving each type and kind of pile will be made at the contract unit price. Such payment will constitute full compensation for all labor, equipment, materials, and all other items necessary and incidental to the completion of the work.

Method 3 For items of work for which specific unit prices are established in the contract, the length of each type and kind of pile driven will be computed to the nearest foot as the difference between the measured length of pile before driving and measured length of pile cut off after driving. Payment for furnishing and driving each type and kind of pile will be made at the contract unit price. Such payment will constitute full payment for all labor, equipment, materials, and other items necessary and incidental to the completion of the work.

Method 4 For items of work for which specific unit prices are established in the contract, the area of sheet pile walls, acceptably placed in accordance and within the neat lines shown on the drawings, will be computed to the nearest square foot. Payment will be made at the contract unit price for each type, kind, and weight of piling. Such payment will constitute full payment for all labor, equipment, materials, and other items necessary and incidental to the completion of the work.

All Methods The following provisions apply to all methods of measurement and payment:

The measurement of the number of linear feet of piles (or number of piles) furnished and the number of piles driven shall include test and tension piles specified in the contract. Piles furnished and driven at the option of the Contractor will not be included. No payment will be made for furnishing or driving pile, including test piles, to replace piles lost or damaged prior to the completion of the contract while in stockpile or during handling and driving.

When load tests are specified, payment for each test will be made at the contract unit price per test. Such payment will constitute full compensation for all labor, equipment, materials, and all other items necessary and incidental to perform the test, except furnishing and driving piling.

When splices are specified, payment for each splice will be made at the contract unit price. Such payment shall constitute full compensation for labor, equipment, materials, and all other items necessary and incidental to the completion of the work.

Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 14 of this specification.

PRESSURE GROUTING

1. APPLICABILITY

Construction Specification 14 is applicable to the drilling and pressure grouting of structure foundations with suspension grouts.

2. MATERIAL SPECIFICATIONS

Material Specification [522](#) and [531](#) are complementary to Construction Specification 14.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Plan and profile of the grouting layout. Include region to be grouted, location and spacing of lines and holes. Show the depth of holes, location, and logs of drill holes used in the geologic investigation.
- b. Mode of drilling (rotary, percussion, or rotary-percussion) and diameter of grout holes.
- c. Inclination of holes (angle to vertical) if inclined holes are required.
- d. Designate the location and distance for transport of core boxes into storage.
- e. Number and depth of check holes to be drilled and mode of drilling.
- f. Details of testing and sampling in over burden, if required. Include method of measurement and payment.
- g. Location and placement details of capping concrete or concrete slabs, if required.
- h. Method of grouting (packer or stage). As a rule, packer grouting is the preferred method unless rock conditions prohibit the seating of packers in the hole. If analysis shows stage grouting must be used, the reasoning for the decision should be documented.
- i. Area boundaries and depth of stages for stage grouting. Depth intervals (lifts) for packer grouting.
- j. Criteria for split spacing (cubic feet of dry solids per linear foot of hole, usually 0.5 cubic foot per foot of hole).
- k. Sequence in which grout hole rows are to be grouted, usually upstream row first.
- l. Design pressures at the collar for various grout mixes and various depth intervals, see chart in Section 13 of the specification.
- m. Limitations and requirements on the sequence of drilling and grouting, usually 50 feet.

- n. Minimum distance to be maintained between grouting and drilling operations, and minimum age of grout at which drilling in grouted holes or adjacent to grouted holes will be permitted, normally 12 hours.
- o. Specify the minimum distance between grouted area and blasting site and maximum allowable blasting intensity. Criteria: Particle velocity maximum of 1 inch per second at the location of the grouted rock.
- p. Minimum distance between grout and water injections, concrete structures, and drains.
- q. Specify type of cement to be used in grout mix and specify starting ratios if different from Section 14.
- r. Specify to which gradation sand is to conform as per gradation limits in Section 2.
- s. Type and quality of admixtures. If calcium chloride is to be used, specify that it shall conform to ASTM D 98. Specify: "high sodium, Wyoming grade bentonite", if bentonite is specified in Section 18.
- t. Type and quality of bulk fillers. (Specify Section 2 gradation limits or other numerical gradation. Note approval of fly ash source, if applicable.)
- u. Pollution Control Measures (PCM) When Construction Specification 5, Pollution Control, does not provide guidance for the grouting operations, include requirements in this specification. PCM are to be installed and maintained by the Contractor to prevent waste grout materials, chemical wastes, and soil from entering the stream. A plan for pollution control is to be submitted by the Contractor to the Engineer for review prior to installation of any measures. After grouting has been completed, pollution control measures are to be removed. A minimum of one sediment basin will usually be required. Cross reference these requirements with Construction Specification 5.
- v. The quantity variation clause applies to pressure grouting. Quantity estimates should not include token amounts but should reflect the best estimate of expected grout take based on site exploration data and engineering geology.
- w. Bid items for mobilization for pressure grouting, if applicable. A separate bid item should be considered if mobilization for grouting equipment will involve a significant amount of work, and grouting is not the principal item of construction work under the contract. If grouting is the main job, a general mobilization item using Construction Specification 8 should be used for all mobilization.
- x. If Construction Specification 94, Contractor Quality Control, is not a part of the contract and this specification is being used in a federal contract, and the Contractor is required to keep detailed records for quality control, modify Section 15, RECORDS by inserting in Section 18, Items of Work and Construction Details, the altered roles of the Engineer and Contractor.

- y. Alternate to (x) above, use Construction Specification 94 and detail the Contractor's Quality Control activities that are required.

4. DISCUSSION OF METHODS

No Methods are outlined in the Specification.

Section 18 shall provide a clear statement of the items listed under Section 17, Measurement and Payment, that will apply to work requirements for measurement and payment purposes.

CONSTRUCTION SPECIFICATION

14. PRESSURE GROUTING

1. SCOPE

The work shall consist of drilling grout holes, exploratory holes and check holes, pressure testing, pressure washing, and injecting suspension grout under pressure, and shall include furnishing of all materials, labor, and equipment as described and specified.

2. MATERIALS

Portland Cement. Portland cement shall conform to the requirements of Material Specification 531 for the specified type. If the cement contains lumps or foreign material which would clog the grouting equipment or interfere with grout injection, it shall be screened through a 100-mesh screen. Cement shall be furnished in bags (94 lb.) unless special equipment is provided for storing, handling, and weighing bulk cement as specified in Section 3 of this specification.

Water. Water used shall be clean and free from injurious amounts of oil, acid, organic matter, or other deleterious substances.

Sand. Sand for grout shall conform to Material Specification 522 and unless otherwise specified, the gradation shall be within the numerical limits in the following table:

<u>Sieve Designation (U.S. Std. Square Mesh)</u>	<u>Percent Passing by Weight</u>
16	100
50	20 – 50
100	10 – 30
200	0 – 5

Sand included in the mix shall be measured in cubic-foot boxes or other volumetric method approved by the Engineer, or by dry unit weight with correction for moisture content.

Bulk Fillers. Bulk fillers other than sand shall be of the type and quality specified in Section 18 of this specification. Bulk fillers included in the mix shall be measured in cubic-foot boxes, or by dry unit weight with correction for moisture content, if applicable.

Admixtures. Admixtures shall be the type and quality specified in Section 18 of this specification.

Storage and Supply. A sufficient quantity of all materials shall be on hand to insure that grouting operations will not be interrupted or delayed. Materials shall be stored and protected at all times and at all locations in such a manner that the quality of the materials is maintained.

3. EQUIPMENT

All drilling and grouting equipment shall be of a type and capacity, and in condition, to perform the work described.

Drilling Equipment. Drilling equipment shall be capable of drilling angle holes up to 45° from vertical, unless otherwise specified in Section 18 of this specification.

For exploratory holes, all drilling equipment used in rock shall be of the rotary type and shall be equipped with hydraulic feed.

Cores shall be drilled with standard ball bearing, swivel type, "N" size, double or triple tube split inner core barrels or equivalent size wire-line coring equipment.

Equipment for drilling grout and check holes shall be of the rotary, percussion, or rotary-percussion type as specified in Section 18 of this specification. No core recovery will be required, and the type of bit used shall be optional. Equipment using air alone for flushing cuttings shall not be used. When percussion drilling equipment using water for flushing cuttings is used, the lifting rate of the flushing water shall be not less than 18 inches per second.

Grouting Equipment. The equipment shall be capable of mixing and pumping grout having a mix ratio, by volume, of one (1) part water, one (1) part cement, and two (2) parts bulk filler, such as sand or fly ash.

Mixers. Unless otherwise specified, mixers shall be of the high speed colloidal type and capable of thoroughly mixing water, cement, and bulk fillers to produce a grout of uniform texture and consistency. Mixers shall match the capacity of the pumping plant.

Holdover Tank. A holdover tank shall be furnished if a single compartment mixer is used. It shall be equipped with mechanical agitators to prevent segregation of the grout, and shall have sufficient capacity to temporarily store the grout and thus provide a continuous supply. The outflow shall pass through a No. 16 wire mesh screen if the grout contains particles or foreign matter that would interfere with its proper flow into the voids it is intended to fill.

Pumps. Grout pumps shall be of the long stroke, multiple piston or the helical screw type. The capacity shall be not less than 3 cubic feet per minute at 200 psi for the maximum grout mix of 1:1:2 (w:c:bf) by volume.

Cement and Fly Ash-Handling Equipment. If bulk cement or fly ash is used, it shall be stored in weather tight bins or silos equipped and arranged to discharge directly into a weighing hopper, and hence, directly into the grout mixer without spillage and without intermediate handling.

Air Supply. The air supply shall meet the requirement of the pumps and shall not be less than 200 cubic feet per minute per plant.

Water Meter. One water meter, of the reset type, graduated in tenths of gallons or hundredths of cubic feet shall be used with each mixer.

Pressure Gauges. One pressure gauge shall be installed at the pump and one at the collar of the hole. Gauges shall be of the non-clogging type or shall be prevented from clogging by using gauge savers or grease. Spare gauges shall be available at the plant at all times.

Hoses, Valves, and Fittings. Hoses, valves, and fittings shall be compatible with the maximum pressures specified. Hose from pump to grout header and return shall not be smaller than 1 1/2-inch (ID), and the pipe between header and packer shall not be smaller than 3/4-inch (ID). Double or single packers may be required for grouting and pressure testing. Packers shall fit tightly in the holes at all testing and grouting pressures.

4. ARRANGEMENT OF GROUTING EQUIPMENT

The arrangement of grouting equipment shall provide a return line from the header back to the mixer or holdover tank, permitting continuous circulation of the grout. The grout pressure shall be controlled at the header or at the end of the return line.

The hose between the take-off at the grout supply line to the header at the hole shall not be longer than 15 feet.

Grouting several holes simultaneously from the same grout pump (multiple header arrangement) will not be permitted.

Each hole shall be equipped with a shutoff valve below the hand coupling union, permitting shutoff at refusal pressure and removal of the header to another hole while still maintaining pressure in the completed hole.

The header arrangement shall include a blow off valve and a control valve, to be used to check hole back pressure prior to header removal, and a return line valve. The header shall be connected to the supply line by means of a U-shaped pipe arrangement or other fashion which prevents fallout of solids into the hole from the bypassing grout during low rates of grout acceptance.

5. COMMUNICATIONS

A suitable voice communications system between individuals at the pump units and the holes shall be maintained by the Contractor.

6. GROUT MIXTURES

Composition. Grout shall consist of a mixture of portland cement, water, sand, bulk filler, and additives, as specified.

Grout mixes and sequences of changes in mix ratio or composition shall be as specified in Section 13 of this specification or as approved by the Engineer.

Mix Ratios. Grout mix ratios will be expressed in cubic feet of water to a bag of cement. Bulk fillers will be expressed in cubic feet to a bag of cement. Other additives will be expressed in percent to a bag of cement and measured in pounds, gallons, or pints.

7. GROUT CAPS AND CONCRETE SLABS

Concrete for grout caps and slabs, if required, shall be placed as shown on the drawings. The concrete shall be a workable mixture of portland cement, fine and coarse aggregates, and water, containing not less than 6 bags of cement per cubic yard of concrete, and not more than 6 gallons of water per bag of cement, including the free moisture of the aggregates.

Portland cement shall conform to the requirements of Material Specification 531 for the type specified. Aggregates shall consist of sound and durable particles and shall conform to the limitations for deleterious substances and the grading requirements of ASTM Specification C 33. Coarse aggregates shall be size 7, 67, 57 or 467 as defined in ASTM Specification C 33.

Batching, mixing, and placing shall be conducted in a manner that will produce a uniform, well-graded, and dense concrete.

When ready-mixed concrete is furnished, the Contractor shall furnish the Engineer a delivery ticket showing the time of loading and the quantities of materials used for each load of concrete. Concrete shall be placed within 1-1/2 hours after introduction of the cement to the aggregates or within 3/4 hours when the temperature of the concrete is 85° F or greater.

Surfaces against which concrete is to be placed shall be cleaned of all soil, loose rock, and other loose material and shall be moist when the concrete is placed.

Concrete shall be placed only when the Engineer is present.

The concrete shall be prevented from drying for a curing period of at least 5 days after it is placed. Exposed surfaces shall be kept continuously moist for the entire period, or shall be coated with an acceptable curing compound as soon as free water has disappeared.

8. DRILLING OVERBURDEN

Unless otherwise specified, holes drilled through overburden shall be cased with steel. Casings shall be removed after completion of the grouting operations unless otherwise approved by the Engineer. Holes in overburden shall be backfilled with grout or a sand-cement mixture or by tamping soil into the holes to approximately

the bulk density of the surrounding overburden, unless otherwise specified in Section 18 of this specification.

9. DRILLING ROCK

The location, inclination, and depth of holes shall be as shown on the drawings or as directed by the Engineer.

The use of rod dope, grease, and other solid or liquid lubricants shall not be permitted.

The Contractor shall perform such exploratory drilling as may be required to determine the condition of the rock prior to grouting and the effectiveness of the grouting operation as the work progresses. All exploratory holes shall be cored and shall be pressure tested when directed by the Engineer. Exploratory holes shall be drilled with an "N" size core barrel as specified in Section 3 of this specification. Rock core samples shall be carefully placed in correct sequence in labeled core boxes furnished by the Contractor. The Contractor shall transport the core boxes to the location designated in Section 18 of this specification.

Unless otherwise specified, grout holes shall have a diameter not less than 2-15/16 inches (NX).

10. WASHING GROUT HOLES

When authorized by the Engineer and prior to grout injection, grout holes shall be washed with water and air to remove mud, drill cuttings, and other materials which will interfere with the grout take of the hole. Grout holes to be washed and the sequence of washing shall be approved by the Engineer. Washing under pressure using packers or pressure testing shall be performed when specified. Washing time for each hole shall be approved by the Engineer.

If mud is moved into a hole by grouting nearby holes after the hole has been washed, the mud will be removed by re-washing the hole.

The air and water pressure will be adjusted to provide the maximum cleaning condition for the holes as determined by the Engineer. Water and air shall be introduced simultaneously under pressure and at the same elevation in the hole. The water pump shall be capable of producing 200 gpm of water at a minimum of 100 psi. The air supply shall be capable of furnishing a minimum of 200 cubic feet per minute at 100 psi.

Unless approved by the Engineer, no holes shall be washed that are within 100 feet of a previously grouted hole unless the grout has been placed for at least 48 hours.

11. PRESSURE TESTING

In holes to be pressure tested, the packer or packers shall be set at intervals as directed by the Engineer. Each interval shall be tested at water pressures up to the specified design grouting pressure for that interval, unless otherwise directed by the Engineer. Pressures exceeding the specified design pressures shall not be applied unless specifically authorized by the Engineer.

The flow shall be read at 1 minute intervals. The test is completed when the rate of take is steady for at least 3 consecutive minutes at the maximum pressure for the section being tested. The flow readings shall be recorded on a form supplied by or approved by the NRCS.

Pressure test equipment shall be calibrated at the site to determine the pressure loss in the equipment at various flow rates and test depths.

Pressure tests and calibration of pressure test equipment shall be performed in the presence of the Engineer.

12. PACKER AND STAGE GROUTING

For packer grouting, the holes shall be drilled to the total depths and shall be grouted in lifts starting at the bottom. If the drill water is lost completely, the hole shall be grouted at that depth and drilling continued not less than 24 hours after grouting. The packer lifts and related pressures shall be as specified except as otherwise directed by the Engineer.

If stage grouting becomes necessary, it shall be performed in successive depth intervals (stages) in each hole beginning at the rock surface and progressing to the deeper stages. All of the holes in a specified area shall be drilled and grouted in each stage before grouting of the succeeding stage is begun. The stages and the grouting pressures for each stage shall be as specified unless otherwise directed by the Engineer.

Each stage of a hole shall be washed with water and air simultaneously and immediately before grouting. Washing under pressure or pressure testing shall be performed as specified in Section 10 of this specification.

13. GROUT INJECTION

The pumping rate shall not exceed 3 cubic feet per minute, unless otherwise approved by the Engineer. Grout pressures shall be as specified in Section 18 of this specification, but shall not exceed the refusal pressures shown in the following table:

GROUT REFUSAL PRESSURES FOR MIX RATIOS

Rock Cover (feet)	Gauge Pressure at Collar in PSI For the Mix Ratios (by volume)							
	1:1:2	1:1:1	1:1:3/5	1:1 W:C	2:1	3:1	5:1	Water
5	1	1	1	1	1	1	2	3
10	1	1	2	2	3	3	4	5
20	1	2	3	5	7	8	9	10
40	8	12	14	17	21	23	26	30
60	22	26	28	34	40	43	46	52
80	36	41	44	52	60	64	68	75
100	50	56	60	70	80	84	90	99

- NOTES: (1) 1:1:3/5 = 5 water : 5 cement : 3 sand
 (2) overburden counts as 50% rock cover,
 (10 feet of overburden = 5 feet of rock cover)
 (3) For depths and mix ratios other than those shown, linear interpolation shall be made to determine maximum pressure.

Grouting, particularly in zones near the surface, shall be accomplished with extreme caution to prevent uplift of the rock or excessive leakage at the surface.

The Contractor shall caulk surface cracks which allow excessive loss of grout. Cracks may be caulked by mechanical means or with fast-setting mortar. If necessary, grouting shall be temporarily suspended or the pressure shall be reduced to permit the caulking of leaks. Accelerators may be added to the grout for the same purpose if approved by the Engineer.

If grout injected into one hole appears in adjacent holes, the interconnected holes shall be plugged temporarily with packers set just above the level at which the grout is entering. Holes grouted by interconnection shall be split spaced.

The quantity of grout prepared in advance shall be kept to a minimum. Grout, which has remained in the mixer or holdover tank with or without agitation for greater than one (1) hour, shall be discarded.

Grout temperatures shall be not lower than 50° F. The grouted soil, rock, or concrete shall be not colder than 40° F when grout is injected and for at least 48 hours thereafter. Insulation or heat shall be applied to the surface for 24 hours prior and 48 hours after grouting if required to keep the soil, rock, or concrete above the minimum required temperature.

When the hole shows signs of refusal, a thinner mix shall be used to prevent or remove clogging.

A hole shall be considered grouted when the grout take at the design pressure is less than one cubic foot of grout in 10 minutes.

If a hole continues to accept grout after a specified amount of the thickest workable grout mixture has been injected, the Engineer may specify a reduced pump speed and/or the use of accelerators, or may direct that the pumping be halted temporarily to permit the grout to set. In which case, the hole shall be flushed with about 5 to 8 cubic feet of water and rested for at least 4 hours.

Grouting shall be discontinued in holes which do not respond to the above procedure and the holes shall be re-drilled and re-grouted later, or the area of high grout absorption shall be grouted from adjacent holes until the design objective has been achieved.

14. GROUTING PROCEDURE

The procedures and grout mixes described below are general guidelines and may be altered in the field by the Engineer to suit the conditions encountered and to meet the design objectives.

Unless on-the-site experience indicates otherwise and in lieu of pressure testing, each stage or lift of a hole to be grouted shall be started with about 15 cubic feet (three batches) of water:cement mix to be no thinner than 5:1 (w:c) by volume, unless otherwise specified in Section 18 of this specification.

If the hole continues to take grout at a pumping rate not to exceed 3 cubic feet per minute and at a pressure equal to or less than specified as refusal pressure, the mix ratio shall be changed to 3:1 (w:c). If the majority of the holes accept the 3:1 without signs of slowdown in the rate of take, holes in that stage or location may be started with a 3:1 instead of the 5:1 mix. A change to a different location or stage may require a return to the 5:1 starter mix.

Grout mixes shall be thickened from 5:1 to 3:1 to 2:1 to 1:1 after which sand and/or fly ash shall be added to the mix in a graduated manner (5:5:1S, 5:5:2S, etc.). The water-cement ratio shall not be less than one.

15. RECORDS

Unless otherwise specified, the Contractor shall keep drilling logs and complete records of all grouting operations. These records include time logs of grout mixes and admixtures used in each stage or lift for each hole, related pressures and pumping rates, backpressures, and observations on excessive leakage and other non-routine conditions. The drilling log shall include date, hole location, depth of rock, and depths to various rock features. Rock features shall be described as hard, soft, weathered, cracks, cavities, etc. The Contractor quality control activities are outlined in Construction Specification 94, when applicable.

Unless otherwise specified, the Contractor shall cooperate in providing all information related to drilling and grouting activities required by the contract.

Unless otherwise specified, one copy of the records shall be provided the Engineer at the completion of each shift.

16. CLEANUP

After grouting is completed, the Contractor shall remove the grouting plant and all related parts, equipment, and supplies from the site, including unused materials and waste.

17. MEASUREMENT AND PAYMENT

For items of work for which specific unit prices or lump sum prices are established in the contract, measurement and payment for pressure grouting will be made as described below. Such payment will constitute full compensation for all labor, materials, equipment, and all other items necessary and incidental to the completion of the work.

Mobilization. Payment for mobilization will be made at the contract lump sum price. Such payment will include compensation for moving grouting equipment and supplies to the site of the work, assembling the plant at the site, moving on the site as work progresses, and removal from the site upon completion of the work. Sixty percent of the lump sum price will be paid when the plant is assembled at the site and grouting work is begun. The remaining 40 percent will be paid after the work is completed, the plant is removed from the site, and cleanup is complete.

Drilling overburden. Drilling overburden will be measured by determining to the nearest foot the total linear feet of accepted hole drilled in the overburden. Payment for drilling overburden will be made at the contract unit price which will include compensation for placing and removing casings.

Drilling Rock. Drilling rock will be measured by determining to the nearest foot the total linear feet of accepted hole of each size drilled in rock without coring. Payment for drilling rock will be made at the contract unit price for each size of hole.

Coring Rock. Coring rock will be measured by determining to the nearest foot the total linear feet of accepted hole of each size cored in rock. Payment for coring rock will be made at the contract unit price for each core size which will include compensation for furnishing and handling the core boxes, storing cores, and recording observations as specified.

Pressure Tests. Pressure testing will be measured by determining the total time to the nearest one-quarter hour that pressure is applied to the holes in making the required tests. One-quarter hour will be added for setting up equipment for each testing period. No extra payment will be made for calibrating pressure test equipment. Payment for pressure tests will be made at the contract unit price.

Washing Grout Holes. Measurement for payment will be determined by the total time, to the nearest one-tenth hour, that water is actually applied to the hole. No

extra payment will be made for setting up equipment. Payment for washing grout holes will be made at the contract unit price.

Connections to Grout Holes. Connections to grout holes will be measured by determining the number of connections made of the grout supply hose to the holes to be grouted. The number of connections for payment will not exceed one per hole for packer grouting or one for each stage for stage grouting, except that if grouting is interrupted to permit the grout to set, one additional connection will be measured for payment each time grouting at the same elevation in the same hole is resumed. Payment for connections to grout holes will be made at the contract unit price.

Placing Grout. Grout placed will be measured to the nearest cubic foot by counting the number of batches of each grout mixture injected in the holes as specified and multiplying by the number of cubic feet per batch. The number of cubic feet per batch for each grout mixture will be determined as the average of the measured volumes of at least three batches of the mixture, or shall be calculated as the sum of the absolute volumes of water, cement, sand and bulk fillers used in the mixture. Absolute volume is defined as:

$$\frac{\text{weight (lb.) of material}}{\text{bulk specific gravity of material X 62.4}}$$

Admixtures shall not be considered in determining batch volume. The weight and specific gravity for sand shall be based on saturated surface dry conditions.

Payment for placing grout will be made at the contract unit price which will include compensation for handling all materials for the purpose of mixing and placing grout, sealing surface leaks, and maintaining grout records. Payment will not be made for grout lost by failure of the Contractor to caulk surface leaks or for grout otherwise wasted due to the actions of the Contractor.

Cement. Cement for grout will be measured on the basis of the number of bags of cement (94 lb.) or equivalent weight of bulk cement used in the grout. Cement used in concrete for capping or other purposes will not be included. Payment for cement will be made at the contract unit price. Payment will not be made for cement in grout wasted because of mechanical failure or due to the actions of the Contractor.

Sand and Bulk Fillers. Sand and bulk fillers will be measured by volume or equivalent weight, adjusted for moisture content where applicable, to the nearest cubic foot of each used in the grouting operation. Payment will be made at the contract unit price for sand and each type of bulk filler specified. Payment will not be made for sand or bulk filler wasted because of mechanical failure or due to the actions of the Contractor.

Admixtures. Liquid admixtures will be measured by volume to the nearest gallon. Dry admixtures will be measured by weight to the nearest pound. Payment for admixtures will be made at the contract unit price for each type of admixture

specified. Payment will not be made for admixtures wasted because of mechanical failure or due to the actions of the Contractor.

Grout Caps and Concrete Slabs. Capping and slab concrete will be measured to the nearest 0.1 cubic yard by determining the combined weights of cement, aggregates, and water used in concrete mixed and placed as specified, and dividing by a unit weight of 4000 lb. per cubic yard. Payment for capping concrete will be made at the contract unit price which will include compensation for furnishing and handling all materials, including cement, and for mixing, transporting, placing, and curing the concrete.

Subsidiary Items. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 18 of this specification.

EXCAVATION

1. APPLICABILITY

Construction Specification 21 is applicable to all types of excavation. The specification defines classes of excavation and includes special requirements for certain types of excavation but does not establish and define all types of excavation. It is intended that the types of excavation be established on a job or project basis, as needed.

The "class" of excavation defines the kind of material to be excavated. The "type" of excavation defines the functional purpose of the excavation. Established types of excavation may include (but are not restricted to):

- a. Foundation Excavation with or without Stripping;
- b. Cutoff, Keyway, or Core Trench Excavation;
- c. Channel Excavation;
- d. Structure Excavation;
- e. Auxiliary Spillway Excavation;
- f. Abutment Shaping Excavation;
- g. Borrow Area Excavation.

Any of the established types may include excavation of materials in either class or may be unclassified. However, the excavation of a given class of material may be more difficult in one type of excavation than in another. These factors must be carefully considered as a basis for establishing types of excavation to be designated on the drawings and listed in the bid schedule.

For projects involving considerable quantities of excavation of different classes of material under conditions that vary in different part of the works, bids must be asked, and payments made, on the basis of both type and class of excavation. For such projects it is necessary that the bid schedule be set up in terms of both type and class of excavation (for example: Channel Excavation, Common; and Channel Excavation, Rock).

For projects involving only one type of excavation and for projects involving small quantities of excavation, it may be sufficient to include only the classes of excavation in the bid schedule.

2. MATERIAL SPECIFICATIONS

There are no material specifications complementary to Construction Specification 21, Excavation.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. The horizontal and vertical extent of each type of excavation. Indicate the vertical extent as approximate where the exact depth required is not known.

- b. Designation and definition of types of excavation.
- c. Excavation pay limits when Method 1, Section 10, is used.
- d. Surface finish requirements, such as grading tolerances. This may be especially important at the crest of an auxiliary spillway.
- e. The location and limits of all borrow areas. Outline all surface grading requirements following completion of borrow material utilization.
- f. The location and limits of all waste areas. When borrow areas serve also as waste areas, coordination of construction activities may be important.
- g. Boring logs and test pit logs pertinent to all areas to be excavated. In addition to descriptions of materials, logs must also include, when it exists, water table elevations and dates of observation. For purposes of the construction drawings, no indications of correlation of materials between logs shall be shown. Interpretation of materials is to be avoided and left to the contractor for determination.
- h. Existing access and haul roads.
- i. Special requirements for dewatering and keeping the excavation dry, with cross reference to Construction Specification 11, [Removal of Water](#), where applicable.
- j. Special requirements for control of blasting, including written plans and approvals, if applicable.
- k. Special requirements for control of erosion, water pollution and air pollution, with cross-reference to Construction Specification 5, [Pollution Control](#), as applicable.
- l. Requirements for control of the size gradation of excavated rock where necessary in order to obtain material of a particular gradation for rock fill or riprap.
- m. Methods of measurement and payment, if the standard specification includes more than one method.
- n. Requirements for concrete to fill voids from over-excavation (refer to Construction Specification 31, [Concrete for Major Structures](#), or 32, [Structure Concrete](#)) if requirements in Section 9 are not adequate.

4. DISCUSSION OF METHODS

a. Section 5, Use of Excavated Materials

- (1) Method 1 is intended for use when the quality, condition and relative location of significant quantities of the materials to be excavated are known to be

suited to the economic construction of the required earthfills and earth backfills, and particularly where alternate sources of material are less desirable or do not exist.

- (2) Method 2 is intended for use when the known data indicate that the use of alternate sources of earthfill materials may result in more economical construction of the required earthfills and earth backfills.

b. Section 6, Disposal of Waste Materials

- (1) Method 1 is intended for use when areas for wasting unsuitable and/or excess materials are available at the site, when the waste fill will beneficially supplement the function of the permanent works or when there is no known market for such waste materials as may be produced.
- (2) Method 2 is intended for use when areas for wasting unsuitable and excess material are not readily available at the site or when there is a known market for such waste materials as may be produced.

c. Section 10, Measurement and Payment

Note in Section 11 when volume calculations other than the average cross-sectional end area method will be used and describe the applicable method. Example - "In lieu of computing excavation volumes by the method of average cross-sectional end areas, the volume may be computed by the prismatic formula method with the assistance of computer aided design program."

- (1) Method 1 is intended for excavations where the pay limits can best be defined on the drawings.
- (2) Method 2 is intended for excavations bounded by simple plane surfaces and constant or gradually varying cross section throughout.
- (3) Method 3 is intended for excavations whose lower limits are determinable only by examination of the materials encountered and where the lower limits have been designated on the drawings as approximate or "to be determined by the Engineer during construction".
- (4) Method 4 is intended for structure excavation bounded by fairly simple plane surfaces where pay limits are not shown on the drawings.

When specifications are prepared using electronic procedures and all but one method are deleted for use in a contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

21. EXCAVATION

1. SCOPE

The work shall consist of the excavation required by the drawings and specifications and disposal of the excavated materials.

2. CLASSIFICATION

Excavation will be classified as common excavation or rock excavation in accordance with the following definitions or will be designated as unclassified.

Common excavation shall be defined as the excavation of all materials that can be excavated, transported, and unloaded by the use of heavy ripping equipment and wheel tractor-scrappers with pusher tractors or that can be excavated and dumped into place or loaded onto hauling equipment by means of excavators having a rated capacity of one cubic yard or larger and equipped with attachments (such as shovel, bucket, backhoe, dragline or clam shell) appropriate to the material type, character, and nature of the materials.

Rock excavation shall be defined as the excavation of all hard, compacted or cemented materials that requires blasting or the use of ripping and excavating equipment larger than defined for common excavation. The excavation and removal of isolated boulders or rock fragments larger than one (1) cubic yard encountered in materials otherwise conforming to the definition of common excavation shall be classified as rock excavation. The presence of isolated boulders or rock fragments larger than one (1) cubic yard will not in itself be sufficient cause to change the classification of the surrounding material.

For the purpose of these classifications, the following definitions shall apply:

Heavy ripping equipment shall be defined as a rear-mounted, heavy duty, single-tooth, ripping attachment mounted on a track type tractor having a power rating of at least 250 flywheel horsepower unless otherwise specified in Section 11.

Wheel tractor-scraper shall be defined as a self-loading (not elevating) and unloading scraper having a struck bowl capacity of at least twelve (12) cubic yards.

Pusher tractor shall be defined as a track type tractor having a power rating of at least 250 flywheel horsepower equipped with appropriate attachments.

3. UNCLASSIFIED EXCAVATION

Excavation designated as "Unclassified Excavation" shall include all materials encountered regardless of their nature or the manner in which they are removed. When excavation is unclassified, none of the definitions or classifications stated in Section 2, CLASSIFICATION, shall apply.

4. BLASTING

The transportation, handling, storage, and use of dynamite and other explosives shall be directed and supervised by person(s) of proven experience and ability who are authorized and qualified to conduct blasting operations.

Blasting shall be done in such a manner as to prevent damage to the work or unnecessary fracturing of the foundation and shall conform to any special requirements in Section 11 of this specification. When specified in Section 11, the Contractor shall furnish the Engineer in writing, a blasting plan prior to blasting operations.

5. USE OF EXCAVATED MATERIALS

Method 1 To the extent they are needed, all suitable materials from the specified excavations shall be used in the construction of required permanent earthfill or rockfill. The suitability of materials for specific purposes will be determined by the Engineer. The Contractor shall not waste or otherwise dispose of suitable excavated materials.

Method 2 Suitable materials from the specified excavations may be used in the construction of required earthfill or rockfill. The suitability of materials for specific purposes will be determined by the Engineer.

6. DISPOSAL OF WASTE MATERIALS

Method 1 All surplus or unsuitable excavated materials will be designated as waste and shall be disposed of at the locations shown on the drawings.

Method 2 All surplus or unsuitable excavated materials will be designated as waste and shall be disposed of by the Contractor at sites of his own choosing away from the site of the work in an environmental acceptable manner and that does not violate local rules and regulations.

7. EXCAVATION LIMITS

Excavations shall comply with OSHA Construction Industry Standards (29CFR Part 1926) Subpart P, Excavations, Trenching, and Shoring. All excavations shall be completed and maintained in a safe and stable condition throughout the total construction phase. Structure and trench excavations shall be completed to the specified elevations and to the length and width required to safely install, adjust, and remove any forms, bracing, or supports necessary for the installation of the work. Excavations outside of the lines and limits shown on the drawings or specified herein required to meet safety requirements shall be the responsibility of the Contractor in constructing and maintaining a safe and stable excavation.

8. BORROW EXCAVATION

When the quantities of suitable materials obtained from specified excavations are insufficient to construct the specified earthfills and earth backfills, additional materials shall be obtained from the designated borrow areas. The extent and depth of borrow pits within the limits of the designated borrow areas shall be as specified in Section 11 or as approved by the Engineer.

Borrow pits shall be excavated and finally dressed to blend with the existing topography and sloped to prevent ponding and to provide drainage.

9. OVER-EXCAVATION

Excavation in rock beyond the specified lines and grades shall be corrected by filling the resulting voids with portland cement concrete made of materials and mix proportions approved by the Engineer. Concrete that will be exposed to the atmosphere when construction is completed shall meet the requirements of concrete selected for use under Construction Specification 31, [Concrete for Major Structures](#), or 32, [Structure Concrete](#), as appropriate.

Concrete that will be permanently covered shall contain not less than five (5) bags of cement per cubic yard. The concrete shall be placed and cured as specified by the Engineer.

Excavation in earth beyond the specified lines and grades shall be corrected by filling the resulting voids with approved compacted earthfill, except that, if the earth is to become the subgrade for riprap, rockfill, sand or gravel bedding, or drainfill, the voids may be filled with material conforming to the specifications for the riprap, rockfill, bedding or drainfill. Prior to correcting an over-excavation condition, the Contractor shall review the planned corrective action with the Engineer and obtain approval of the corrective measures.

10. MEASUREMENT AND PAYMENT

For items of work for which specific unit prices are established in the contract, the volume of each type and class of excavation within the specified pay limits will be measured and computed to the nearest cubic yard by the method of average cross-sectional end areas or by methods outlined in Section 11 of this specification. Regardless of quantities excavated, the measurement for payment will be made to the specified pay limits, except that excavation outside the specified lines and grades directed by the Engineer to remove unsuitable material will be included. Excavation required because unsuitable conditions result from the Contractor's improper construction operations, as determined by the Engineer, will not be included for measurement and payment.

Method 1 The pay limits shall be as designated on the drawings.

Method 2 The pay limits shall be defined as follows:

- a. The upper limit shall be the original ground surface as it existed prior to the start of construction operations except that where excavation is performed within areas designated for previous excavation or earthfill the upper limit shall be the modified ground surface resulting from the specified previous excavation or earthfill.
- b. The lower and lateral limits shall be the neat lines and grades shown on the drawings.

Method 3 The pay limits shall be defined as follows:

- a. The upper limit shall be the original ground surface as it existed prior to the start of construction operations except that where excavation is performed within areas designated for previous excavation or earthfill the upper limit shall be the modified ground surface resulting from the specified previous excavation or earthfill.
- b. The lower and lateral limits shall be the true surface of the completed excavation as directed by the Engineer.

Method 4 The pay limits shall be defined as follows:

- a. The upper limit shall be the original ground surface as it existed prior to the start of construction operations except that where excavation is performed within areas designated for previous excavation or earthfill the upper limit shall be the modified ground surface resulting from the specified previous excavation or earthfill.
- b. The lower limit shall be at the bottom surface of the proposed structure.
- c. The lateral limits shall be 18-inches outside of the outside surfaces of the proposed structure or shall be vertical planes 18-inches outside of and parallel to the footings, whichever gives the larger pay quantity, except as provided in d, below.
- d. For trapezoidal channel linings or similar structures that are to be supported upon the sides of the excavation without intervening forms, the lateral limits shall be at the under side of the proposed lining or structure.
- e. For the purposes of the definitions in b, c, and d, above, any specified bedding or drainfill directly beneath or beside the structure will be considered to be a part of the structure.

All Methods The following provisions apply to all methods of measurement and payment.

Payment for each type and class of excavation will be made at the contract unit price for that type and class of excavation. Such payment will constitute full compensation

for all labor, materials, equipment, and all other items necessary and incidental to the performance of the work, except that extra payment for backfilling over-excavation will be made in accordance with the following provisions:

Payment for backfilling over-excavation, as specified in Section 9 of this specification, will be made only if the excavation outside specified lines and grades is directed by the Engineer to remove unsuitable material and if the unsuitable condition is not a result of the Contractor's improper construction operations as determined by the Engineer.

Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 11 of this specification.

EARTHFILL

1. **APPLICABILITY**

Construction Specification 23 is applicable to all types of earthfill, including fill sections constructed of rocky soils and embankments constructed of soft or friable rock which is expected to break down during compaction.

2. **MATERIAL SPECIFICATIONS**

There are no material specifications complementary to Construction Specification 23.

3. **ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS**

- a. Complete plans and cross sections of the required earthfills and earth backfills.
- b. Pay limits, where applicable.
- c. Borrow areas or other sources of material(s).
- d. Designation and description of the types of materials required in the various parts of the work.
- e. Maximum allowable size of rock particles.
- f. Special requirements for foundation preparation.
- g. Maximum layer thickness before compaction for earthfill. (Table A-23 of these Instructions may be used as a guide. Table A-23 gives upper limits for the general classes of material listed. The specified maximum layer thickness may have to be substantially less than the tabulated value to obtain adequate compaction.)
- h. Maximum layer thickness before compaction for earth backfill by manually directed power tampers. (The maximum thickness that can be adequately compacted depends upon the tampers and upon the soil being placed, varying from about four (4) inches for plastic clays to about eight (8) inches for coarse grained material of low plasticity.)
- i. Special instructions for sectional or phased construction where applicable.
- j. Allowable range of moisture content for each item. For example:
 - (1) "The moisture content of the fill matrix at the time of compaction shall be neither less than two (2) percent below optimum moisture content nor more than two (2) percent above optimum moisture content."

(2) "The moisture content of the fill material shall be maintained within the limits required to: (a) prevent bulking or dilatance of the material under the action of the hauling or compacting equipment; (b) prevent the adherence of the earthfill material to the treads and tracks of the equipment; and, (c) ensure the crushing and blending of the soil clods and aggregations into a reasonably homogeneous mass."

- k. Compaction class for each item. (Table A-23 may be used as a guide.)
- l. For Class A compaction: Compaction test method and required percent of maximum density. Typical compaction test results, if applicable.
- m. For Class B compaction: Minimum mass density.
- n. For Class C compaction: Type of roller; minimum weight or contact pressure of roller; minimum vibrating force and frequency for vibrating roller; minimum number of passes.
- o. Special rapid methods for moisture control, (quick dry, speedy, alcohol, nuclear gauge), if used. These methods are only to be used on soils where they prove to be a reliable approximation to ASTM D 2216. When rapid methods are used, a reference to the procedure to be followed should be included.
- p. When the "family of curves" and the one-point Proctor is the intended method for soil density standard determination and verification, it should be referenced and so specified in Section 10.
- q. Special requirements, where applicable, for placing earth backfill adjacent to structures; such as, reduced compactive effort for high, thin walled structures. This may include monitoring stresses and wall movements and/or specifying minimum in-place concrete strength requirements before the forms or other supports are removed or earth backfilling commences. Minimum in-place concrete strength requirements shall be determined by the designer and clearly stated.
- r. Required minimum strength of concrete, determined according to Section 6, for starting compaction of backfill adjacent to structures, if applicable. Use of minimum strength is encouraged over minimum times listed in Section 6.
- s. Methods of measurement and payment.
- t. Embedded structures or other elements whose volume will be excluded from the earthfill volume for payment. Major items may be listed for exclusion. The cost of measuring, computing, checking, record keeping, etc. must clearly justify the exclusion.

- u. Special requirements pertaining to furnishing and applying water, including designated source and details of ownership and water rights, if applicable, and including water quality requirements if quality may be a concern.
- v. Special requirements for control of erosion, water pollution, and air pollution, with appropriate cross-reference to Construction Specification [5, Pollution Control](#).
- w. Surface finish requirements, such as completed surface grade tolerances.

4. DISCUSSION OF METHODS

a. Section 9, Measurement and Payment

Note in Section 10 when volume calculations other than by the average cross-sectional end area method will be used and describe the applicable method. Example - "In lieu of computing volumes by the method of average cross-sectional end areas, the volume may be computed by the prismatic formula method with the assistance of computer aided design program."

- (1) Method 1 is intended for structure earth backfill and other cases where pay limits can best be shown on the drawings.
- (2) The selected methods for pay limits must be compatible with those selected for use in Construction Specification [21, Excavation](#).
- (3) Method 6 or 7 must be used with any or all Methods 1 through 5.
 - (a) Method 6 is intended for use when no separate payment is to be made for water.
 - (b) Method 7 is intended for use with Construction Specification [10, Water for Construction](#), when the Contractor is to be paid under a separate item for the water needed to bring the earthfill and earth backfill materials to the specified moisture content.

When specifications are prepared using electronic procedures and all but one method are deleted for use in a contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

TABLE A – 23

Grading Characteristics of Soil Fill Material		Approximate Compaction Classes	Maximum Layer Thickness (Before Compaction)			
% > No. 4	% Fines (Passing #200)		Tamping Roller	Pneumatic Roller	Vibrating Roller	40000 lb. Track Trctr.
0 – 35	Over 5	A	9"	9"	---	---
	Under 5	A B, C	9" ---	12" 18"	24" 30"	--- 12"
35 – 65	25 – 50	A B, C	9" 9"	12" 18"	24" 24"	--- ---
	5 – 25	A B, C	--- ---	12" 18"	24" 24"	--- ---
	Under 5	B, C	---	24"	24"	18"
Over 65	Over 5	B, C	---	18"	24"	---
	Under 5	B, C	---	24"	24"	18"

Note: Tabulated values are upper limits. Actual maximum layer thickness for uniform compaction of a given soil material may be substantially lower. Maximum size of rock or rock fragments should not exceed 2/3 of the layer thickness prior to compaction. Soil plasticity should be a consideration.

For Weathered or weakly indurated rock materials:

For materials such as shales, schists, disintegrated granite, soft sandstone, and siltstone, the appropriate compaction classes depend upon the degree of breakdown under the action of the excavating and compacting equipment. The maximum layer thickness before compaction must be determined on the basis of special laboratory tests or field compaction tests or both. Field test fills should be considered to determine the least effort required to meet minimum density requirements.

CONSTRUCTION SPECIFICATION

23. EARTHFILL

1. SCOPE

The work shall consist of the construction of earth embankments, other earthfills, and earth backfills required by the drawings and specifications.

Earthfill is composed of natural earth materials that can be placed and compacted by construction equipment operated in a conventional manner.

Earth backfill is composed of natural earth materials placed and compacted in confined spaces or adjacent to structures (including pipes) by means of hand tamping, manually directed power tampers or vibrating plates, or equivalent.

2. MATERIALS

All fill materials shall be obtained from required excavations and designated or approved borrow areas. The selection, blending, routing and disposition of materials in the various fills shall be subject to approval by the Engineer.

Fill materials shall contain no frozen soil, sod, brush, roots or other perishable materials. Rock particles larger than the maximum size specified for each type of fill shall be removed prior to compaction of the fill.

The types of materials used in the various fills shall be as listed and described in the specifications and drawings.

3. FOUNDATION PREPARATION

Foundations for earthfill shall be stripped to remove vegetation and other unsuitable materials or shall be excavated as specified.

Except as otherwise specified, earth foundation surfaces shall be graded to remove surface irregularities and shall be scarified parallel to the axis of the fill or otherwise acceptably scored and loosened to a minimum depth of two (2) inches. The moisture content of the loosened material shall be controlled as specified for the earthfill, and the surface materials of the foundation shall be compacted and bonded with the first layer of earthfill as specified for subsequent layers of earthfill.

Earth abutment surfaces shall be free of loose, uncompacted earth in excess of two inches in depth normal to the slope and shall be at such a moisture content that the earthfill can be compacted against them to produce a good bond between the fill and the abutments.

Rock foundation and abutment surfaces shall be cleared of all loose materials by hand or other effective means and shall be free of standing water when fill is placed upon them. Occasional rock outcrops in earth foundations for earthfill, except in dams and other structures designed to restrain the movement of water, shall not

require special treatment if they do not interfere with compaction of the foundation and initial layers of the fill or the bond between the foundation and the fill.

Foundation and abutment surfaces shall be not steeper than one (1) horizontal to one (1) vertical unless otherwise specified. Test pits or other cavities shall be filled with compacted earthfill conforming to the specifications for the earthfill to be placed upon the foundation.

4. PLACEMENT

Earthfill shall not be placed until the required excavation and foundation preparation have been completed and the foundation has been inspected and approved by the Engineer. Earthfill shall not be placed upon a frozen surface, nor shall snow, ice, or frozen material be incorporated in the earthfill matrix.

Earthfill shall be placed in approximately horizontal layers. The thickness of each layer before compaction shall not exceed the maximum thickness specified in Section 10 or shown on the drawings. Materials placed by dumping in piles or windrows shall be spread uniformly to not more than the specified thickness before being compacted.

Hand compacted earth backfill shall be placed in layers whose thickness before compaction does not exceed the maximum thickness specified for layers of earth backfill compacted by manually directed power tampers.

Earth backfill shall be placed in a manner which will prevent damage to the structures and will allow the structures to assume the loads from the earth backfill fill gradually and uniformly. The height of the earth backfill adjacent to a structure shall be increased at approximately the same rate on all sides of the structure.

Earthfill and earth backfill in dams, levees and other structures designed to restrain the movement of water shall be placed so as to meet the following additional requirements:

- a. The distribution of materials throughout each zone shall be essentially uniform, and the earthfill shall be free from lenses, pockets, streaks or layers of material differing substantially in texture, moisture content, or gradation from the surrounding material. Zone earthfills shall be constructed concurrently unless otherwise specified.
- b. If the surface of any layer becomes too hard and smooth for proper bond with the succeeding layer, it shall be scarified parallel to the axis of the fill to a depth of not less than two (2) inches before the next layer is placed.
- c. The top surfaces of embankments shall be maintained approximately level during construction, except that a crown or cross-slope of approximately two (2) percent shall be maintained to ensure effective drainage, and except as otherwise specified for drainfill or sectional zones.

- d. Dam embankments shall be constructed in continuous layers from abutment to abutment except where openings to facilitate construction or to allow the passage of stream flow during construction are specifically authorized in the contract.
- e. Embankments built at different levels as described under (c) or (d) above shall be constructed so that the slope of the bonding surfaces between embankment in place and embankment to be placed is not steeper than three (3) feet horizontal to one (1) foot vertical. The bonding surface of the embankment in place shall be stripped of all material not meeting the requirements of this specification, and shall be scarified, moistened and re-compacted when the new earthfill is placed against it. This is to insure a good bond with the new earthfill and to obtain the specified moisture content and density at the contact of the in place and new earthfills.

5. CONTROL OF MOISTURE CONTENT

During placement and compaction of earthfill and earth backfill, the moisture content of the materials being placed shall be maintained within the specified range.

The application of water to the earthfill materials shall be accomplished at the borrow areas insofar as practicable. Water may be applied by sprinkling the materials after placement on the earthfill, if necessary. Uniform moisture distribution shall be obtained by disking.

Material that is too wet when deposited on the earthfill shall either be removed or be dried to the specified moisture content prior to compaction.

If the top surface of the preceding layer of compacted earthfill or a foundation or abutment surface in the zone of contact with the earthfill becomes too dry to permit suitable bond it shall either be removed or scarified and moistened by sprinkling to an acceptable moisture content prior to placement of the next layer of earthfill.

6. COMPACTION

Earthfill. Earthfill shall be compacted according to the following requirements for the class of compaction specified:

Class A Compaction. Each layer of earthfill shall be compacted as necessary to provide the density of the earthfill matrix not less than the minimum density specified in Section 10 or identified on the drawings. The earthfill matrix is defined as the portion of the earthfill material finer than the maximum particle size used in the compaction test method specified.

Class B Compaction. Each layer of earthfill shall be compacted to a mass density not less than the minimum density specified.

Class C Compaction. Each layer of earthfill shall be compacted by the specified number of passes of the type and weight of roller or other equipment specified, or by an approved equivalent method. Each pass shall consist of at least one passage of the roller wheel or drum over the entire surface of the layer.

Earth backfill. Earth backfill adjacent to structures shall be compacted to a density equivalent to that of the surrounding in-place earth materials or adjacent required earthfill or earth backfill. Compaction shall be accomplished by means of hand tamping or manually directed power tampers, plate vibrators, walk-behind, miniature, or self-propelled rollers. Unless otherwise specified, heavy equipment including backhoe mounted powertampers, or vibrating compactors and manually directed vibrating rollers, shall not be operated within two (2) feet of any structure. Towed or self-propelled vibrating rollers shall not be operated within five (5) feet of any structure. Compaction by means of drop weights operating from a crane or hoist will not be permitted.

The passage of heavy equipment will not be allowed: (1) over cast-in-place conduits prior to 14-days after placement of the concrete; (2) over cradled or bedded pre-cast conduits prior to seven (7) days after placement of the concrete cradle or bedding; or (3) over any type of conduit until the backfill has been placed above the top surface of the structure to a height equal to one-half the clear span width of the structure or pipe or two (2) feet, whichever is greater, except as may be specified in Section 10.

Compacting of earth backfill adjacent to structures shall not be started until the concrete has attained the strength specified in Section 10 for this purpose. The strength will be determined by compression testing of test cylinders cast by the Contractor's quality control personnel for this purpose and cured at the work site in the manner specified in ASTM C 31 for determining when a structure may be put into service.

When the required strength of the concrete is not specified as described above, compaction of earth backfill adjacent to structures shall not be started until the following time intervals have elapsed after placement of the concrete.

<u>Structure</u>	<u>Time Interval</u>
Vertical or near-vertical walls with earth loading on one side only	14 days
Walls backfilled on both sides simultaneously	7 days
Conduits and spillway risers, cast in-place (with inside forms in place)	7 days
Conduits and spillway risers, cast-in place (inside forms removed)	14 days

<u>Structure</u>	<u>Time Interval</u>
Conduits, pre-cast, cradled	2 days
Conduits, pre-cast, bedded	1 day
Cantilever outlet bents (backfilled both sides simultaneously)	3 days

7. REWORKING OR REMOVAL AND REPLACEMENT OF DEFECTIVE EARTHFILL

Earthfill placed at densities lower than the specified minimum density or at moisture contents outside the specified acceptable range of moisture content or otherwise not conforming to the requirements of the specifications shall be reworked to meet the requirements or removed and replaced by acceptable earthfill. The replacement earthfill and the foundation, abutment and earthfill surfaces upon which it is placed shall conform to all requirements of this specification for foundation preparation, approval, placement, moisture control and compaction.

8. TESTING

During the course of the work, the Engineer will perform such quality assurance tests as are required to identify materials; determine compaction characteristics; determine moisture content; and determine density of earthfill in-place. Tests performed by the Engineer will be used to verify that the earthfills conform to contract requirements of the specifications and not as a replacement for the Contractor's quality control program.

Densities of earthfill requiring Class A compaction will be determined in accordance with ASTM D 1556, D 2167, D 2922 or D 2937 except that the volume and moist weight of included rock particles larger than those used in the compaction test method specified for the type of fill will be determined and deducted from the volume and moist weight of the total sample prior to computation of density or if using the nuclear gauge, added to the specified density to bring it to the measure of equivalent composition for comparison. The density so computed will be used to determine the percent compaction of the earthfill matrix. Unless otherwise specified, moisture content will be determined by one of the following methods: ASTM D 2216, D 3017, D 4643, D 4944, or D 4959.

9. MEASUREMENT AND PAYMENT

For items of work for which specific unit prices are established in the contract, the volume of each type and compaction class of earthfill and earth backfill within the specified zone boundaries and pay limits will be measured and computed to the nearest cubic yard by the method of average cross-sectional end areas or by methods outlined in Section 10 of this specification. Unless otherwise specified in Section 10, no deduction in volume will be made for embedded items such as, but

not limited to: conduits, inlet structures, outlet structures, embankment drains, sand diaphragm and outlet, and their appurtenances.

The pay limits shall be as defined below, with the further provision that earthfill required to fill voids resulting from over-excavation of the foundation, outside the specified lines and grades, will be included in the measurement for payment only where such over-excavation is directed by the Engineer to remove unsuitable material and where the unsuitable condition is not a result of the Contractor's improper construction operations as determined by the Engineer. Earthfill beyond the specified lines and grades to backfill excavation required for compliance with OSHA requirements will be considered subsidiary to the earthfill bid item(s).

Method 1 The pay limits shall be as designated on the drawings

Method 2 The pay limits shall be the measured surface of the foundation when approved for placement of the earthfill and the specified neat lines of the earthfill surface.

Method 3 The pay limits shall be the measured surface of the foundation when approved for placement of the earthfill and the measured surface of the completed earthfill.

Method 4 The pay limits shall be the specified pay limits for excavation and the specified neat lines of the earthfill surface.

Method 5 The pay limits shall be the specified pay limits for excavation and the measured surface of the completed earthfill.

Method 6 Payment for each type and compaction class of earthfill and earth backfill will be made at the contract unit price for that type and compaction class of earthfill. Such payment will constitute full compensation for all labor, materials, equipment and all other items necessary and incidental to the performance of the work.

Method 7 Payment for each type and compaction class of earthfill and earth backfill will be made at the contract unit price for that type and compaction class of earthfill. Such payment will constitute full compensation for all labor, materials, equipment and all other items necessary and incidental to the performance of the work, except furnishing, transporting, and applying water to the foundation and earthfill materials. Water applied to the foundation and earthfill materials will be measured and payment will be made as specified in Construction Specification 10.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 10 of this specification.

INSTRUCTIONS FOR USE OF CONSTRUCTION SPECIFICATION 24

DRAINFILL

1. APPLICABILITY

Construction Specification 24 is applicable to the placing of drainfill in all types of structure drainage systems such as:

- a. Drainage systems installed beneath concrete structures, lining or pavements;
- b. Wall drains for concrete structures;
- c. Embankment drainage systems;
- d. Interceptor drains installed adjacent to structures;
- e. Foundation drains.

2. MATERIAL SPECIFICATIONS

Material Specification [521](#) is complementary to Construction Specification 24.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. The location, extent, and dimensions of each drain.
- b. The grading limits of each type of drainfill.
- c. The allowable percentage of material (non-plastic) passing No. 200 Sieve.
- d. The source of drainfill materials, when applicable.
- e. Specifications for control of moisture if required. If water is to be added and is to be included in a separate pay item for water, add the statement in Section 9: "Water applied to the drainfill material will be measured and payment will be made as specified in Construction Specification [10, Water for Construction](#)".
- f. Class of compaction. Also specify the weight and number of passes of the compacting equipment required, if more than the minimum amounts specified in Section 6. (Class A provides for control of compaction by minimum density requirements determined by ASTM D698 for fine grain material. Classes I, II and III specify the method of compaction. Relative density tests during construction usually should be made in connection with the method specifications to evaluate the compaction being accomplished and be compared to test data outlined in ASTM D4254. Class I is intended for use where highest densities are required, Class II is intermediate, and Class III may be used for wall drains in uncompacted backfill or for other applications where strength is not important.

Specify in Section 9 the ASTM D698 procedure to be modified to consist of one point value for maximum dry density determined on an oven-dried representative

sample of the drainfill material. The procedure shall be repeated three times to obtain an average value for the one point.

When specifying Class II compaction, note in Section 9 the method (a, b, or c) that applies. Note also if one or more of the methods are to be excluded.

- g. Special requirements for placing drainfill adjacent to new concrete as set forth in Section 4.

4. DISCUSSION OF METHODS

a. Section 2, Materials

- (1) Method 1 is intended for use in specifications for drainage systems in areas where commercial aggregate is available in sufficient quantity to meet project needs.
- (2) Method 2 is intended to be used in specifications for drainage systems in areas where the Contractor will need to process the material from designated sources.

b. Section 8, Measurement and Payment.

- (1) Method 1 is intended for use when for use when quantities are determined from volume measurements and payment is made to the nearest cubic yard.
- (2) Method 2 is intended for use when quantities are determined by weight and payment is by the ton.

When specifications are prepared using electronic procedures and all but one method are deleted for use in a contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

24. DRAINFILL

1. SCOPE

The work shall consist of furnishing, placing and compacting drainfill required in the construction of structure drainage systems.

2. MATERIALS

Method 1 Drainfill materials shall conform to the requirements of Material Specification 521. A minimum of thirty (30) days prior to delivery of materials to the site, the Contractor shall inform the Engineer in writing of the source(s) from which drainfill material will be obtained. The Contractor shall provide the Engineer free access to the source(s) for the purpose of obtaining samples for testing.

Method 2 Drainfill materials shall be sand, gravel, or crushed stone or mixtures thereof obtained from the specified sources. They shall be selected as necessary to avoid the inclusion of organic matter, clay balls, excessive fine particles or other substances that would interfere with their free-draining properties.

3. BASE PREPARATION

Foundation surfaces and trenches shall be clean and free of organic matter, loose soil, foreign substance, and standing water when the drainfill is placed. Earth surfaces upon or against which drainfill will be placed shall not be scarified.

4. PLACEMENT

Drainfill shall not be placed until the subgrade has been inspected and approved by the Engineer. Drainfill shall not be placed over or around pipe or drain tile until the installation of the pipe or tile has been inspected and approved.

Drainfill shall be placed uniformly in layers not to exceed twelve (12) inches thick prior to compaction. When compaction is accomplished by manually controlled equipment, the layers shall not exceed eight (8) inches thick. The material shall be placed in a manner to avoid segregation of particle sizes and to insure the continuity and integrity of all zones. No foreign materials shall be allowed to become intermixed with or otherwise contaminate the drainfill.

Traffic shall not be permitted to cross over drains at random. Equipment crossovers shall be maintained, and the number and location of such crossovers shall be established and approved prior to the beginning of drainfill placement. Each crossover shall be cleaned of all contaminating materials and shall be inspected and approved by the Engineer prior to the placement of additional drainfill material.

Any damage to the foundation surface or the trench sides or bottom occurring during placement of drainfill shall be repaired before drainfill placement is continued.

The upper surface of drainfill constructed concurrently with adjacent zones of earthfill shall be maintained at a minimum elevation of one (1) foot above the upper surface of adjacent earthfill.

Drainfill over and/or around pipe or drain tile shall be placed in a manner to avoid any displacement in line or grade of the pipe or tile.

Drainfill shall not be placed adjacent to structures until the concrete has attained the strength specified in Section 9 of this specification. The strength shall be determined by compression testing of concrete test cylinders cast and field cured at the project site in accordance with ASTM Method C 31 for determining when a structure may be placed into service.

When the required strength of the concrete is not specified as described above, placement of drainfill adjacent to concrete structures shall not be commenced until the following item intervals have elapsed following placement of the concrete:

<u>Structure Type</u>	<u>Time Interval</u>
Vertical or near-vertical wall with earth loading on one side only (Retaining walls and counterforts)	14 days
Walls backfilled on both sides simultaneously	7 days
Conduits and galleries, cast-in-place (with inside forms in place) (inside forms removed)	7 days 14 days
Conduits, precast, cradled	2 days
Conduits, precast, bedded	1 day
Cantilever outlet bents backfilled on both sides simultaneously	3 days

5. CONTROL OF MOISTURE

The moisture content of drainfill materials shall be controlled as specified in Section 9 of this specification. When the addition of water is required, it shall be applied in a manner to avoid excessive wetting to adjacent earthfill. Except as specified in Section 9 of this specification, control of moisture content will not be required.

6. COMPACTION

Drainfill shall be compacted according to the following requirements for the class of compaction specified:

Class A Compaction. For drainfill materials with more than 70% passing the 3/4 inch sieve, each layer of drainfill shall be compacted to a minimum dry density of not less than the density specified in Section 9 of this specification as determined by ASTM D698.

For drainfill materials with 70% or less passing the 3/4 inch sieve, each layer of drainfill shall be compacted to a relative density of not less than 70% as determined by ASTM D4254.

Class I Compaction. Each layer of drainfill shall be compacted by a minimum of two (2) passes, over the entire surface, with a steel-drum vibrating roller weighing a minimum of five (5) tons and exerting a vertical vibrating force of not less than 20,000 pounds at a minimum frequency of 1200 times per minute, or by an approved equivalent method.

Class II Compaction. Each layer of drainfill shall be compacted by one of the following methods or by an approved equivalent method (A pass is defined as at least one complete coverage of the roller wheel, tire or drum over the entire surface for each layer):

- a. A minimum of two (2) passes over the entire surface with a pneumatic-tired roller exerting a minimum pressure of 75 pounds per square inch (psi).
- b. A minimum of four (4) passes over the entire surface with the track of a crawler-type tractor weighing a minimum of 20 tons.
- c. Controlled movement of the hauling equipment so that the entire surface is traversed by not less than one tread track of the loaded hauling equipment.

Class III Compaction. No compaction will be required beyond that resulting from the placing and spreading operations.

When compaction other than Class III compaction is specified, materials placed in trenches or other locations inaccessible to heavy equipment shall be compacted by means of manually controlled pneumatic or vibrating tampers as specified in Section 9 of this specification.

Heavy equipment shall not be operated with 2 feet of any structure. Vibrating rollers shall not be operated within 5 feet of any structure. Compaction by means of drop weights operating from cranes, hoists, or similar equipment will not be permitted.

7. TESTING

The Contractor shall conduct such tests as necessary to verify that the drainfill materials and the in place drainfill meets the specification requirements.

The Engineer shall be granted access to perform such tests as are required to verify that the drainfill materials and the drainfill in place meets the requirements of the

specifications. These tests are not intended to provide the Contractor with information needed to assure that the materials and workmanship meet the specification requirements. These verification tests will not relieve the Contractor of the responsibility of performing required tests for that purpose.

8. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established in the contract, the volume of drainfill within the neat lines shown on the drawings will be measured and computed to the nearest cubic yard. Where the Engineer directs placement of drainfill outside the neat lines to replace unsuitable foundation material, the volume of such drainfill will be included. The volume included will only be to the extent that the unsuitable condition is not a result of the Contractor's improper construction operation in the determination of the Engineer.

Payment for drainfill will be made at the contract unit price for each type of drainfill, complete in place. Except as otherwise specified in Section 9 of this specification, such payment will constitute full compensation for all labor, equipment, materials, and all other items necessary and incidental to the performance of the work.

Method 2 For items of work for which specific unit prices are established in the contract, the quantity of drainfill placed within the specified limits will be computed to the nearest 0.1 ton by actual weight. Where the Engineer directs placement of drainfill outside the neat lines to replace unsuitable foundation material, the weight of such drainfill will be included. The weight included will only be to the extent that the unsuitable condition is not a result of the Contractor's improper construction operation in the determination of the Engineer.

Payment for drainfill will be made at the contract unit price for each type of drainfill, complete in place. Except as otherwise specified in Section 9 of this specification, such payment will constitute full compensation for all labor, equipment, materials, and all other items necessary and incidental to the performance of the work.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not included in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 9 of this specification.

ROCKFILL

1. APPLICABILITY

Construction Specification 25 is applicable to rockfill constructed of hard, durable rock with sufficiently open grading to drain freely. It does not apply to riprap slope protection nor to earthfill constructed of rocky soils or of soft rock which is expected to breakdown during compaction activities.

2. MATERIAL SPECIFICATIONS

There are no material specifications complementary to Construction Specification 25.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Complete plans and cross-sections of the required fills. Include any required construction tolerances measured from the lines and grades shown on the drawings.
- b. Zoning plans, including gradation requirements for materials in each zone.
- c. Specifications for bedding.
- d. Pay limits where applicable.
- e. The source of each type of fill.
- f. Screening or other processing requirements.
- g. Specifications for wetting during placement and compaction, if required. If water is to be added and is to be included in the separate pay item for water, add the statement: Water applied to the fill material will be measured and payment will be made as specified in Construction Specification 10, [Water for Construction](#).
- h. Class of compaction for rockfill. Specify more passes or heavier equipment if test fills or other sources of information indicate the need for it. (Class I is intended for use where the highest degree of compaction is required, Class II is intermediate, and Class III is for use where no special compaction is needed.)

When specifying Class II compaction, note in Section 10 the method (a, b, or c) that applies. Note also if one or more of the methods are to be excluded.
- i. Class of compaction for bedding. Also specify more passes or heavier equipment if more than minimum amounts specified in Section 8 may be needed.

4. DISCUSSION OF METHODS

- a. Section 5, Placement.

- (1) Method 1 is intended for use whenever the grading of materials within the fill is not a critical element of the design.
- (2) Method 2 is intended for use when the piping or cracking potential of the core zone is a critical element of the design or when the percentage of large rock is relatively low and special slope protection is desired.

CONSTRUCTION SPECIFICATION

25. ROCKFILL

1. SCOPE

The work shall consist of the construction of rockfill zones of embankments and other rockfills required by the drawings and specifications, including bedding where specified.

2. MATERIALS

Materials for rockfill and bedding shall be obtained from the specified sources, unless otherwise specified in Section 10 of this specification. The materials shall be excavated, selected, processed, and handled as necessary to conform to the specified gradation requirements.

3. FOUNDATION PREPARATION

Foundations for rockfill shall be stripped to remove vegetation and other unsuitable materials or shall be excavated as specified.

Except as otherwise specified, earth foundation surfaces shall be graded to remove surface irregularities, and test pits or other cavities shall be filled with compacted earthfill of approximately the same kind and density as the adjacent foundation material.

Rock foundation surfaces shall be cleared of all loose materials not conforming to the specifications for the rockfill.

Abutments for rockfill zones of embankments shall be prepared as specified above for foundations.

Rockfill and/or bedding shall not be placed until the foundation preparation is completed and the foundation and excavations have been inspected and approved.

4. BEDDING

When a bedding layer beneath rockfill is specified, the bedding material shall be spread uniformly on the prepared subgrade surfaces to the depth indicated. Compaction of the bedding material shall be as specified in Section 10 of this specification.

5. PLACEMENT

Method 1 The rock shall be dumped and spread into position in approximately horizontal layers not to exceed three (3) feet in thickness. It shall be placed in a manner to produce a reasonably homogeneous stable fill that contains no segregated pockets of large or small fragments or large unfilled spaces caused by bridging of the larger rock fragments.

Method 2 The rock shall be dumped and spread into position in approximately horizontal layers not to exceed three (3) feet in thickness. The rock shall be placed so that the completed fill shall be graded with the smaller rock fragments placed in the inner portion of the embankment and the larger rock fragments placed on the outer slopes. Rock shall be placed in a manner that will produce a stable fill that contains no large unfilled spaces caused by bridging of the larger fraction.

6. CONTROL OF MOISTURE

The moisture content of rockfill material shall be controlled as specified in Section 10 of this specification. When the addition of water is required, it shall be applied in a manner to avoid excessive wetting of adjacent earthfill. Except as specified in Section 10 of this specification, control of the moisture content will not be required.

The moisture content of the bedding material shall be controlled to ensure that bulking of the sand materials does not occur during compaction operations.

7. COMPACTION OF ROCKFILL

Rockfill shall be compacted as described below for the class of compaction specified or by an approved equivalent method.

Class I Compaction. Each layer of fill shall be compacted by a minimum of four (4) passes, over the entire surface, with a steel-drum vibrating roller having a minimum weight of five (5) tons and exerting a vertical vibrating force of not less than 20,000 pounds at a frequency not less than 1200 times per minute.

Class II Compaction. Each layer of fill shall be compacted by a minimum of four (4) passes over the entire surface by a track of a crawler-type tractor weighing a minimum of twenty (20) tons.

Class III Compaction. No compaction will be required beyond that resulting from the placing and spreading operations.

Heavy equipment shall not be operated within two (2) feet of any structure. Vibrating rollers shall not be operated within five (5) feet of any structure. Compaction by means of drop weights operating from a crane, hoist or similar equipment will not be permitted.

When compaction other than Class III compaction is specified, rockfill placed in trenches or other locations inaccessible to heavy equipment shall be compacted by means of manually controlled pneumatic or vibrating tampers or by equivalent methods approved by the Engineer.

8. COMPACTION OF BEDDING

Bedding shall be compacted according to the following requirements for the Class of compaction specified:

Class A Compaction. Each layer of bedding shall be compacted to a relative density of not less than 70 percent as determined by ASTM Method D 4254.

Class I Compaction. Each layer of bedding shall be compacted by a minimum of two (2) passes, over the entire surface, with a steel-drum vibrating roller weighing a minimum of five (5) tons and exerting a vertical vibrating force not less than 20,000 pounds at a frequency not less than 1200 times per minute, or an approved equivalent method.

Class II Compaction. Each layer of bedding shall be compacted by one of the following methods or by an equivalent method approved by the Engineer:

- a. A minimum of two (2) passes, over the entire surface, with pneumatic rubber-tired roller exerting a minimum pressure of 75 pounds per square inch (psi). A pass is defined as at least one passage of the roller wheel, track, tire or drum over the entire surface of the bedding layer.
- b. A minimum of four (4) passes, over the entire surface, with the track of a crawler-type tractor weighing a minimum of 20 tons.
- c. Controlled movement of the hauling equipment so that the entire surface is traversed by a minimum of one (1) tread track of the loaded equipment.

Class III Compaction. No compaction will be required beyond that resulting from the placing and spreading operations.

Heavy equipment shall not be operated within two (2) feet of any structure. Vibrating rollers shall not be operated within five (5) feet of any structure. Compaction by means of drop weights operating from a crane, hoist or similar equipment will not be permitted.

When compaction other than Class III is specified, bedding placed in trenches or other locations inaccessible to heavy equipment shall be compacted by means of manually controlled pneumatic or vibrating tampers or by equivalent methods approved by the Engineer.

9. MEASUREMENT AND PAYMENT

For items of work for which specific unit prices are established in the contract, the volume of each type of rockfill, including bedding, with the zone boundaries and limits specified on the drawings or established by the Engineer will be measured and computed to the nearest cubic yard by the method of average cross-sectional end areas.

Payment for each type of rockfill will be made at the contract unit price for that type of fill. Except as otherwise specified in Section 10 of this specification, such payment will constitute full compensation for all labor, equipment, materials, and all

other items necessary and incidental to the performance of the work, including furnishing, placing and compacting the bedding material.

Compensation for any type of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 10 of this specification.

INSTRUCTIONS FOR USE OF CONSTRUCTION SPECIFICATION 26

TOPSOILING

1. APPLICABILITY

Construction Specification 26 is applicable to the furnishing and spreading of topsoil to selected areas of the construction site for the purpose of establishing vegetative cover to minimize soil erosion and provide aesthetic improvement.

2. MATERIAL SPECIFICATIONS

No material specifications are complementary to Construction Specification 26.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Limits of source areas for obtaining topsoil.
- b. Limits of areas on which topsoil is to be spread.
- c. Depth of topsoil layer following the spreading operation.
- d. Limits and locations for stockpile areas, if critical.
- e. Limitation of rock sizes to be included in the topsoil to be spread.
- f. Restriction of woody vegetation that may be included in the topsoil to be spread.
- g. Note in the Measurement and Payment section if the measurements will be slope measured or horizontal measurements for use in computing the area covered.
- h. Extent of compaction required for the topsoil.

4. DISCUSSION OF METHODS

The methods in Section 5, Spreading, and Section 6, Measurement and Payment, are self-explanatory.

When progress payments are anticipated, outline in Section 7 the procedures that will be implemented to determine progress amounts.

When specifications are prepared using electronic procedures and all but one method are deleted for use in a contract specification, delete from the next to last paragraph "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text. Also, delete from the last paragraph "All Payment Methods" and left justify the remaining text.

CONSTRUCTION SPECIFICATION

26. TOPSOILING

1. SCOPE

The work shall consist of furnishing and spreading topsoil to specified depths at locations shown on the drawings.

2. QUALITY OF TOPSOIL

Topsoil shall consist of friable surface soil reasonably free of grass, roots, weeds, sticks, rocks or other unsuitable materials. Additional quality requirements, if any, are contained in Section 7 of this specification.

3. FURNISHING

Method 1 Topsoil shall be salvaged from designated earth surfaces that will be disturbed by construction activities. After designated sites have been cleared and grubbed, the topsoil shall be removed from the designated areas and shall be stockpiled at locations shown on the drawings or acceptable to the Engineer. Unsuitable materials encountered during removal of topsoil shall be disposed of at locations shown on the drawings or approved by the Engineer, or otherwise hauled and disposed of at locations removed from the construction site. The Contractor is responsible for complying with all local rules and regulations and the payment of any and all fees that may result from the disposal at locations outside the construction work limits.

Method 2 Topsoil shall be furnished from an off-site source designated by the Contractor. The Engineer shall be granted access to the source for inspection and acceptance prior to delivery to the site. Test results and samples shall be provided when specified in Section 7 of this specification.

4. STOCKPILING

Stockpiles of topsoil shall not conflict with the requirements of Construction Specification 5, [Pollution Control](#), when made a part of this contract.

5. SPREADING

Method 1 Spreading shall not be conducted when the ground or topsoil is frozen, excessively wet or otherwise in a condition detrimental to uniform spreading operations. Surfaces designated to receive a topsoil application shall be lightly scarified just prior to the spreading operation.

Following the spreading operation, the topsoil surface shall be left reasonably smooth and without ruts or surface irregularities that could contribute to concentrated water flow down slope.

Method 2 Spreading shall not be performed when the ground or topsoil is frozen, excessively wet or otherwise in a condition detrimental to uniform spreading

operations. Surfaces designated to receive a topsoil application shall be lightly scarified just prior to the spreading operation. Where compacted earthfills are designated to be topsoiled, the topsoil shall be placed concurrently with the earthfill and shall be bonded to the compacted fill with the compacting equipment.

Following the spreading operation, the topsoil surface shall be left reasonably smooth and without ruts or surface irregularities that could contribute to concentrated water flow down slope.

6. MEASUREMENT AND PAYMENT

Method 1 The total surface(s) covered by topsoil will be measured and the area(s) computed to the nearest square yard. Payment for furnishing and placing topsoil will be made at the contract unit price.

Method 2 The total surface(s) covered by topsoil, except the surface area(s) of embankments, levees, dikes and other earthfills will not be included for payment, will be measured and the area(s) computed to the nearest square yard.

Payment for topsoil spread on the surfaces of embankments, levees, dikes and other earthfills will be included in the measurement and payment for that item of earthfill where topsoil application occurred.

Method 3 For items of work for which specific unit prices are established in the contract, the volume of topsoil furnished and spread will be computed to the nearest cubic yard by the method of average cross-sectional end areas from surveys of the excavated topsoil stockpile or, if not stockpiled, cross-sectional surveys of the borrow area(s). Payment for furnishing and spreading topsoil will be made at the contract unit price.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 6 of this specification.

All Payment Methods Payment will constitute full compensation for all labor, equipment, materials and all other items necessary and incidental to the completion of the work, including excavating, stockpiling, hauling, and spreading, including the wasting of unsuitable excavated material.

INSTRUCTIONS FOR USE OF CONSTRUCTION SPECIFICATION 27

DIVERSIONS AND WATERWAYS

1. APPLICABILITY

Construction Specification 27 is applicable to diversion and waterway construction where the extent of earth excavation and embankment installations is considered minor.

2. MATERIAL SPECIFICATIONS

There are no material specifications complementary to Construction Specification 27.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Location of diversions) and/or waterways) in plan view.
- b. Typical cross section(s) for diversion and/or waterway.
- c. Locations of special borrow area(s) and waste or disposal area(s), if required.
- d. Profile when structure (diversion or waterway) location is known.
- e. Clear and concise information needs to be provided in the specifications to ensure bid item integrity. This is especially true when other earthwork construction specifications are being used in the adjacent areas.

4. DISCUSSION OF METHODS

a. Section 6, Measurement and Payment

When specifications are prepared using electronic procedures and all but one method are deleted for use in a contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

27. DIVERSIONS AND WATERWAYS

1. SCOPE

The work shall consist of all excavations, shaping, grading, and earthfills required to construct the diversions and waterways as shown on the drawings or as staked in the field.

2. MATERIAL

The earth materials used in constructing the earthfill portions of the diversions and/or waterways shall be suitable materials obtained from required excavations or earth materials obtained from designated borrow areas. Material for earthfills shall be free from frozen material, brush, roots, sod, stones over six (6) inches in diameter or other objectionable material(s).

3. FOUNDATION PREPARATION

Foundations for earthfill shall be stripped to remove vegetation and other unsuitable materials or shall be excavated as specified.

Except as otherwise specified, earth foundation surfaces shall be graded to remove surface irregularities and shall be scarified parallel to the axis of the earthfill or otherwise acceptably scored and loosened to a minimum depth of two (2) inches. The moisture content of the loosened material shall be controlled as specified for the earthfill, and the surface materials of the foundation shall be compacted and bonded with the first layer of earthfill as specified for subsequent layers of earthfill.

Earth abutment surfaces shall be free of loose, uncompacted earth in excess of two inches in depth normal to the slope and shall be at such a moisture content that the earthfill can be compacted against them to produce a good bond between the earthfill and the abutments.

4. PLACEMENT

Earthfill material shall not be placed until the required foundation preparation is complete, inspected, and approved for placement. Earthfill shall not be placed upon frozen surfaces. Earthfill shall be placed in horizontal layers not exceeding nine (9) inches in thickness. The moisture content of the earthfill materials shall be sufficient to obtain firm and suitable compaction. Compaction shall be obtained by routing the hauling and spreading equipment over the earthfill material in such a manner that the entire surface of each layer will be traversed by not less than one track tread of the loaded equipment, or equivalent methods approved by the Engineer.

5. EXCAVATION

Excavation shall be to the lines and grades shown on the drawings and/or as staked in the field. All surplus and/or unsuitable material will be designated as waste and

shall be disposed of at locations shown on the drawings or at a location approved by the Engineer.

6. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established in the contract, the length of waterway and/or diversion will be determined to the nearest linear foot by measurement along the centerline of the waterway and/or diversion. Such payment will constitute full compensation for all labor, materials, equipment, and all other items necessary and incidental to the performance of the work.

Method 2 For items of work for which specific lump sum prices are established in the contract, the quantity of waterway and/or diversion will not be measured for payment. Payment for waterways and/or diversions will be made at the contract lump sum price and shall constitute full compensation for all labor, materials, equipment, and all other items necessary and incidental to the performance of the work.

Method 3 The pay limits for excavation and earthfill shall be as designated on the drawings. Payment for excavation and earthfill to construct the waterways and/or diversions will be separately measured and computed to the nearest cubic yard by the method of average cross-sectional end areas. Payment for excavation and/or earthfill will be made at the unit price bid and shall constitute full compensation for all labor, materials, equipment, and all other items necessary and incidental to the performance of the work.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 7 of this specification.

INSTRUCTIONS FOR USE OF CONSTRUCTION SPECIFICATION 28

LIME-TREATED EARTHFILL

1. APPLICABILITY

Construction Specification 28 is applicable to the treatment of clayey soils for the construction or repair of earthfills for dams, dikes, and similar engineering works using hydrated lime.

2. MATERIAL SPECIFICATIONS

Material Specification [593](#) is complementary to Construction Specification 28.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Work limits of area to be treated and processing area.
- b. Treatment procedures or sequence of operations if different or in addition to those in this basic specification.
- c. Type of lime to be used.
- d. Rate of application of lime. This is expressed as a percentage of dry weight of the soil.
- e. Source of soil to be treated.
- f. Location and thickness of zone to be treated.
- g. Maximum layer thickness before compaction. (Refer to Instruction for use of Construction Specification [23](#).)
- h. Maximum layer thickness before compaction for earth backfill compacted by manually directed power tampers. (Same Reference as (g.) above.)
- i. Compaction Class.
- j. Construction Specification [5](#), [Pollution Control](#), shall address the following: weather for spreading, location of work area, storage of materials, disposal of waste materials and containers.
- k. Special equipment needed.
- l. Construction Specification [23](#), [Earthfill](#), needs to be included.
- m. Measurement and payment for lime by the ton as a separate bid item.

4. DISCUSSION OF METHODS

a. Section 6, Lime Application

- (1) Method 1 is intended for dry application of lime.
- (2) Method 2 is intended for the application of lime as a water slurry mix.

b. Section 11, Measurement and Payment

- (1) Method 1 is intended for cases where pay limits can best be shown on the drawings.
- (2) Method 2 through Method 5 are self-explanatory.
- (3) Method 6 or 7 must be used with any or all Methods 1 through 5.
 - (a) Method 6 is intended for use when no separate payment is to be made for water.
 - (b) Method 7 is intended for use with Construction Specification [10, Water for Construction](#), when the Contractor is to be paid under a separate item for the water.

When specifications are prepared using electronic procedures and all but one method are deleted from use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

28. LIME-TREATED EARTHFILL

1. SCOPE

The work shall consist of furnishing lime, mixing lime with soil, curing and placing the lime treated soil.

2. MATERIALS

Soil material shall be obtained from the designated area(s). The selection of the material shall be as outlined in Section 12 of this specification. Soil material shall contain no frozen soil, sod, brush, roots, or other perishable materials. Rock particles larger than the maximum size specified for each type of earthfill shall be removed prior to treatment operations.

Water shall be clean and free from injurious amounts of oil, acid, alkali, organic matter, or other deleterious substances.

Hydrated lime shall meet the requirements of Material Specification [593](#).

3. EQUIPMENT

All equipment necessary for the proper construction of the work shall be on the work site prior to the start of lime treatment operations. Unless otherwise specified, mixing equipment shall include the combined use of heavy disk plows and high speed rotary mixers. Disks shall be at least 24-inches in diameter and rotary mixers shall be capable of mixing lifts at least nine (9) inches thick traveling at a minimum speed of four (4) m.p.h. and covering a minimum width of six (6) feet.

All equipment used to convey or transport lime to or on the work-site shall be covered or enclosed so as to avoid lime dust problems.

4. SITE PREPARATION

The Contractor shall prepare, mix, and cure the lime treated earth material in the area(s) shown on the drawings.

Prior to start of lime treatment operations, the processing area used for mixing and curing shall be stripped of topsoil and graded to a relatively smooth and uniform surface.

After the area is no longer required for mixing and curing, it shall be re-graded as required, disked to a depth of four (4) inches, and covered uniformly with the removed topsoil.

5. LIME PROPORTIONING

The amount of lime shall be as specified in Section 12 of this specification. Adjustment in the amount of lime may be required as the work progresses and shall be adjusted as requested and approved by the Engineer.

6. LIME APPLICATION

Lime shall not be applied when the temperature is below 40° F or is expected to drop below 40° F within 24-hours. Lime will not be applied during high wind conditions that hinder effective application or causes pollution by drift off site.

Method 1 Hydrated lime shall be uniformly applied in dry form on the soil surface at a rate that will attain the specified proportioning and lightly sprinkled with water to minimize dusting and blowing.

Method 2 Hydrated lime shall be mixed with water to form a slurry prior to application to the soil surface. The slurry shall consist of a mixture of one ton of lime to a minimum volume of 500 gallons of water. Agitation shall be accomplished through integral paddles, re-circulating pumps or a combination of these devices. The lime and water shall be maintained as a uniform mixture until application to the soil surface.

The slurry shall be uniformly applied to the soil surface at a rate that will attain the specified proportioning. The slurry shall be applied under pressure through spray bars.

7. MIXING

The soil, lime, and water shall be mixed by disking and use of rotary mixers until a uniform mixture is obtained. During initial mixing with dry lime, a minimum of two cycles of water application followed by mixing with disks and high speed rotary mixers shall be accomplished.

The depth of the lift for treatment shall be no greater than that depth that can be effectively mixed by the equipment. The cycle of watering and mixing shall continue until the soil, lime and water mixture has been thoroughly processed to a uniform mixture without lumps of soil and/or lime. When mixing is complete, the water content of the mix shall not be less than standard optimum water for the soil-lime mixture, when tested in accordance with ASTM D 698, Procedure A.

After mixing, the lime treated layer shall be sealed to minimize evaporation loss, lime carbonation, and excessive wetting from rainfall or other sources. Sealing shall be accomplished by lightly compacting the surface of the treated layer with a pneumatic tire or smooth wheel roller or by other methods approved by the Engineer.

The mixing of lime, soil and water shall be completed within the same workday it is started.

8. PLACEMENT

Lime-treated earthfill shall not be placed until the required excavation and foundation preparation have been completed and the foundation has been inspected and approved by the Engineer. Earthfill shall not be placed upon a frozen surface, nor shall snow, ice, or frozen material be incorporated in the earthfill.

Immediately before placement of lime-soil mixture, the subgrade shall be scarified and moistened to create a water content that shall allow suitable bonding of lime-soil mixture. Surface free water shall not be present during placement operations.

Lime-treated earthfill shall be placed in approximately horizontal layers. The thickness of each layer before compaction shall not exceed the maximum thickness specified in Section 12 or shown on the drawings. Materials placed by dumping in piles or windrows shall be spread uniformly to not more than the specified thickness before being compacted.

During placement and compaction of the lime-soil mixture, the moisture content of the materials being placed shall be maintained within the specified range.

The water content of the mixture at the time of placement and compaction shall not be less than standard optimum moisture when tested in accordance with ASTM D 698, Procedure A.

9. COMPACTION

Lime-treated earthfill shall be compacted in accordance with Section 6 of Construction Specification [23, Earthfill](#), for the specified class.

10. CURING

The lime and soil mixture shall be cured a minimum of 72-hours unless otherwise specified in Section 12. The water content of the mixture shall be maintained at or above standard optimum water content during the curing period by sprinkling with water, re-mixing, and resealing.

After the required curing time has occurred and prior to use as earthfill, the treated material shall be thoroughly re-mixed. Final mixing shall be accomplished in a manner that all non-slaked lime particles retained on the No. 4 sieve are removed, the remaining material shall have all clods reduced in size to meet the following gradation:

Minimum passing 2-inch sieve = 100 percent

Minimum passing No. 4 sieve = 60 percent

11. MEASUREMENT AND PAYMENT

For items of work for which specific unit prices are established in the contract bid schedule:

- (1) The quantity of lime used for lime treatment will be measured to the nearest ton by actual weight, and
- (2) The volume of lime stabilized earthfill within the specified zone boundaries and pay limits shown on the drawings will be measured and computed to the nearest cubic yard by the method of average cross-sectional end areas. Unless otherwise specified, no deduction in volume will be made for embedded conduits and appurtenances.

The pay limits for lime-treated earthfill shall be as defined below, with the further provision that lime stabilized earthfill required to fill voids resulting from over-excavation of the foundation and/or placed outside the specified lines and grades will be included in the measurement for payment only where such placement is approved by the Engineer. Such approval will only be granted for the purpose of filling over-excavation that results from the removal of unsuitable material and where placement outside the lines and grades were not a result of Contractor's improper construction operations as determined by the Engineer.

Method 1 The pay limits shall be as designated on the drawings.

Method 2 The pay limits shall be the measured surface of the foundation when approved for placement of lime treated earthfill and the specified neat lines of the earthfill surface.

Method 3 The pay limits shall be the measured surface of the foundation when approved for placement of lime treated earthfill and measured surface of the completed earthfill.

Method 4 The pay limits shall be the specified pay limits for excavation and specified neat lines of the earthfill surface.

Method 5 The pay limits shall be the specified pay limits for excavation and measured surface of the completed earthfill.

Method 6 Payment for the lime treated earthfill will be made at the contract unit price for that type of earthfill. Such payment will constitute full compensation for all labor, materials, equipment, and all other items necessary and incidental to the performance of the work, including stripping topsoil, grading, and spreading topsoil over the processing area following completion of lime treated earthfill activities. No separate payment will be made for water applied to the foundation and used for preparing hydrated lime.

Method 7 Payment for lime treated earthfill will be made at the contract unit price for that type of earthfill. Such payment will constitute full compensation for all labor, materials, equipment, and all other items necessary and incidental to the performance of the work, including stripping topsoil, grading, and spreading topsoil over the processing area following completion of lime treated earthfill activities. It does not include furnishing, transporting, and applying water to the foundation and earthfill materials. Water applied to the foundation and earthfill materials will be measured and payment made as specified in Construction Specification 10, Water for Construction.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 12 of this specification.

SOIL-CEMENT

1. APPLICABILITY

Construction Specification 29 is applicable to all soil-cement fills.

2. MATERIAL SPECIFICATIONS

The following specifications are complementary to Construction Specification 29:

- a. [Portland Cement](#). Material Specification [531](#)
- b. [Curing Compound \(For Concrete\)](#). Material Specification [534](#)

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Complete plans and cross-sections of the required soil-cement fills.
- b. Borrow areas or other sources of materials. Any grading and shaping requirements of borrow areas.
- c. Soil-cement soil gradation and Atterberg limits.
- d. Cement content of the soil-cement mixture.
- e. The cement type and types of admixtures.
- f. The required pozzolan content.
- g. Allowable range of moisture content of the soil-cement mixture at the time of compaction.
- h. Compaction requirement for subgrade and soil-cement.
- i. The maximum compacted layer thickness.
- j. Pay limits where applicable.
- k. The method of curing process required. If a concrete curing compound is designated, specify "type" of curing compound required.
- l. Minimum capacity of the mixing plant, if applicable.
- m. Any special instructions about the use of soil materials that do not have similar gradation and Atterberg limits to those tested.
- n. All surfaces that are to be bonding surfaces need to be identified: i.e., soil-cement surfaces that are to receive an overlying layer of soil-cement or concrete that requires bonding of the two materials.

- o. The minimum strength of soil-cement determined by the design investigation using available borrow materials and the cement content specified.
- p. If required, specify in Section 15 the durability requirements as outlined in ASTM D 559 and D 560 to evaluate alternative design mixes as provided in Section 2(b).

4. DISCUSSION OF METHODS

- a. Methods in Section 5, Design of Soil-Cement Mixture, and Section 6, Mixing, are self-explanatory.
- b. Section 12, Protecting and Curing
 - (1) Method 1 is an environmentally sound, economical curing process that will provide either a clear, or an opaque white, moisture barrier.
 - (2) Method 2 will provide the best environment for curing, but is likely to be the most expensive. It is suggested for small areas or to reduce shrinkage cracking to the least extent.
 - (3) Method 3 is adaptable for smaller areas and offers the economy to reuse sheeting. Windy conditions may disrupt this curing method.
- c. Section 14, Measurement and Payment
 - (1) Method 1 is for use when cement is included in the unit price for soil-cement.
 - (2) Method 2 is for use when the cement is paid for as a separate unit priced item apart from the soil-cement.
- d. Sections 5, 6, 12, and 14

When specifications are prepared using electronic procedures and all but one method are deleted for use in a contract specification, delete the following and left justify the remaining text:

Section 5 and Section 12, "All Methods"

Section 6, "All Methods The following provisions apply to all methods of mixing."

Section 14, "All Methods The following provisions apply to all methods of measurement and payment."

CONSTRUCTION SPECIFICATION

29. SOIL CEMENT

1. SCOPE

The work shall consist of the furnishing, placing, compacting, and curing a mixture of soil material, portland cement, and water. The mixture shall be uniformly mixed, blended, compacted, finished, and cured as specified. It shall conform to the lines, grades, thicknesses, and cross section(s) shown on the drawings.

2. MATERIALS

Soil materials shall be obtained from the required excavations or designated borrow locations and shall meet the requirements outlined in this Section.

Deleterious materials such as sod, brush, or roots shall be separated from soil materials during the selection, blending, and routing operations. Rock particles larger than two (2) inches in any dimension shall be removed prior to mixing.

Soil materials, cement content, and moisture content other than those specified in Section 15 may be used as approved by the Engineer. Proposed alternatives must meet one of the following requirements to be considered:

- (a) If the soil material to be used has gradation and Atterberg limits similar to the soils specified, the same cement content and water content shall be used. The Contractor shall provide gradation and Atterberg limit test data from a qualified soil testing laboratory verifying gradation and Atterberg limits.
- (b) If the soil materials do not have gradation and Atterberg limits similar to the soils specified, the Contractor shall provide soil-cement durability tests, moisture-density relations data, Atterberg limits, and gradation tests from a qualified soil testing laboratory. The soil-cement mix ratio and water content shall also be provided by the laboratory. As a minimum, the following durability tests shall be provided: ASTM D 559 and ASTM D 560. The moisture-density relations are to be in accordance with ASTM D 558. The tests must indicate a soil-cement of a quality equal to or exceeding the quality specified.

Portland cement shall conform to the requirements of Material Specification 531 for the specified type. Mixing of different brands or types of cement will not be permitted.

Portland cement shall be furnished in bags, barrels, or bulk. Bagged cement that is stored at the job site shall be used in the same order as the deliveries arrived on the site. Each shipment of bagged cement shall be handled and stored so that it may be readily distinguished from other shipments. Emptied cement bags shall be disposed of by the Contractor at off-site locations selected by the Contractor. Burning of emptied cement bags is permitted if identified on the burning permit as an allowable activity.

Water used in mixing or curing soil-cement shall be clean and free from injurious amounts of oil, acid, alkali, organic matter, or other deleterious substances, and shall meet the requirements for water as specified in ASTM C 94.

Pozzolanic Materials, when used, shall comply with the requirements of ASTM C 618 Class C or F, Specifications for Fly Ash, and Raw or Calcined Natural Pozzolan, except the loss on ignition shall not exceed 3.0 percent.

Curing compounds, when used, shall conform to the requirements of Material Specification 534 for the type of curing compound specified. Application of the curing compound shall be in accordance with Section 12 of this specification and the manufacturer's recommendations.

3. OPERATIONS OF PITS OR STOCKPILES OF SOIL MATERIALS

All work required in the opening and operation of borrow areas or stockpiles shall be performed by the Contractor. The borrow areas or stockpiles shall be opened in such a manner as to expose a near vertical face of the soil material for a suitable working depth. Exposed cut faces shall not exceed five feet in height without benching back if it poses a threat to construction personnel and/or others. The Contractor shall conform to OSHA Construction Industry Standards (29 CFR Part 1926) Subpart P, Excavations, Trenching, and Shoring during all excavation operations.

Material shall be excavated in successive vertical cuts extending across the pit or stockpile. When approved by the Engineer, successive horizontal cuts on a horizontal oriented working face may be permitted in homogeneous soils. All pockets or strata of unsuitable materials not meeting the quality requirements specified in Section 2, Material, shall be wasted. The method of operating the pit or stockpile and the blending of materials shall be adjusted as necessary to obtain material conforming to the specifications. Upon completion of the work, the pits shall be graded and dressed to minimize erosion and to provide free drainage.

4. FOUNDATION PREPARATION

Before soil-cement processing commences, the subgrade placement area shall be graded, shaped, and compacted in conformance with the lines and grades shown on the drawings. The subgrade shall firmly support the construction equipment. Immediately prior to the placement of the soil-cement, the compacted subgrade surface shall be moistened to approximately the same moisture content as specified for the soil-cement, and shall be kept moist until the soil-cement is placed.

5. DESIGN OF SOIL-CEMENT MIXTURE

General. The materials and proportions of the soil-cement mixture shall constitute the "job-mix". After a job-mix has been approved, the source, character, or grading of the soil and the type, brand, or quantity of cement or pozzolanic material shall not be changed without prior approval of the Engineer. A change in materials or

proportions requires the establishment of a new job-mix supported by evidence, as required for the initial job-mix, that the proposed new materials and mix proportions will produce soil-cement of the strength specified.

The use of calcium chloride or other accelerants or antifreeze compounds will not be permitted unless approved by the Engineer.

Method 1. The Contractor shall determine the mix proportions and submit the job-mix design, along with the supporting test results to the Engineer for approval prior to incorporating any of the material into the work. The brand of cement and the location of the soil material source shall be included with the job-mix design data. The mix design shall be such that the soil-cement meets or exceeds the minimum compressive strength specified. A new mix design shall be submitted for approval any time the Contractor requests a change in materials or a proportioning of materials from that given in the approved mix design. In no case will the Engineer's review and approval of a mix design relieve the Contractor of responsibility to provide soil-cement meeting the contract specifications.

A maximum of fifteen (15) percent of the total weight of cement may be replaced with fly ash at a rate of 1.2 pounds of fly ash per pound of cement replaced.

Method 2. The Contractor shall furnish the soil, fly ash, cement, and moisture content as specified in Section 15 of this specification. During the course of the work, the Engineer may adjust the job-mix proportions as needed to achieve the specified compressive strength.

All Methods. The percent of cement to be used in the mix will be determined by dividing the weight of cement by the oven dry weight of the soil material.

6. MIXING

The mixing plant shall produce a mixture of soil, cement, and water that is uniform in color and at the required moisture and cement content throughout. The plant shall be equipped with measurement devices that will proportion the mix in the specified quantities. Prior to use, all measurement devices shall be calibrated and certified by a qualified technician approved by the Engineer. The actual quantities of the mix shall not vary more than two (2) percent from the approved job-mix quantities, unless otherwise approved. The moisture content shall be the percentage of moisture in the mixture at the time of compaction.

The Engineer shall have full and free access to the mixing plant at all times for inspection of the plant's operation and for sampling the soil-cement mixture and its components.

Method 1. Mixing of the soil, cement (including fly ash), and water shall be accomplished in a stationary mixing plant. The plant may be either a batch type or a continuous flow type design. The plant may use either weight or volume proportioning. The scale or metering devices shall be sensitive to one (1) percent of

the maximum load that may be required or imposed. The mixer shall be a pugmill, revolving-blade, or rotary-drum system.

Facilities for efficiently storing, handling, and proportioning unmixed materials shall be provided at the plant.

Method 2. Mixing of the soil, cement (including fly ash), and water shall be accomplished in a truck mixer. The mixer shall meet the requirements for truck mixers contained in ASTM C 94.

Method 3. Mixing of the soil-cement shall be accomplished in place. Mixing of the soil, cement (including fly ash), and water shall be accomplished by a single or multiple transverse shaft mixer, a traveling pugmill, or similar equipment approved by the Engineer. A motor grader or similar equipment will not be acceptable in lieu of the mixing equipment specified.

Soil material to be mixed in place shall be formed into windrows or divided into known grid areas. If windrows are used, they shall be prepared to a known size with a sizing device. The tops of the windrows shall be flattened or slightly trenched to receive the cement.

The cement quantity necessary to meet the specified cement to soil ratio shall be distributed uniformly on the windrowed soil or over the prepared grid areas. After spreading, cement that has been displaced, or is found to be less than that specified, shall be properly adjusted or replaced prior to starting mixing operations.

The mixing operation shall be accomplished in such a manner that there are no unmixed seams of soil between layers. Excessive streaking of the soil cement below the layer being mixed will not be allowed.

All Methods. The following provisions apply to all methods of mixing. The mixing time shall be controlled so that all ingredients shall be mixed as long as necessary to ensure a thorough, uniform, and homogeneous mixture of soil, cement, pozzolanic material (if used), and water. Mixing time shall be adjusted based on tests and field determinations. The mixing time shall be considered as the interval between the time the cement contacts the soil and water and the time the mixture leaves the mixing unit or when the mixer speed is reduced to the agitating speed. The soil and cement shall be mixed sufficiently to prevent cement balls from forming before the water is added. The water may be applied through the mixing machine or separately by approved pressure distributing equipment.

Soils containing plastic silt or clay lumps larger than one (1) inch shall be pulverized or screened out of the raw soil prior to mixing.

7. TRANSPORTING

The soil-cement mixture shall be transported from the mixing plant to the site of placement in vehicles having tight, clean, and smooth beds or mixer trucks. Haul time shall not exceed thirty (30) minutes.

The Contractor shall protect the soil-cement mixture if transported during unfavorable weather. Any material excessively wet by precipitation will be subject to rejection.

Equipment shall not be operated on a finished and compacted layer of soil-cement, except where specifically permitted. Any damage resulting to the finished surfaces of the soil-cement from such an operation shall be repaired by the Contractor at no cost to the owner.

Earth ramps crossing over completed soil-cement must have a minimum compacted thickness of two (2) feet. Where ramps are constructed over soil-cement that is not to finished grade, all foreign materials and the uppermost one (1) inch of the top layer of soil-cement must be removed prior to the continuation of the soil-cement installation.

8. PLACEMENT

Soil-cement shall not be placed until the required excavations and preparation of the foundation are completed and the foundation has been inspected and approved by the Engineer.

Equipment for spreading the soil-cement mixture shall be suitable for the purpose and shall be operated in such a manner as to produce a reasonably smooth, uniform surface. The equipment shall be controllable so as to produce uniform layers not more than the specified maximum thickness. The layer of soil-cement, or each successive lift when layering is required, shall be spread and compacted as soon as possible after the preceding layer is completed and approved. Soil-cement shall be placed in horizontal layers or layers conforming to the plane of the subgrade.

When the time between completion of compaction on a layer and start of placement of the next layer is greater than two (2) hours, the Contractor shall scarify the surface to a depth of one (1) inch at a maximum spacing of twelve (12) inches unless specified otherwise in Section 15 or approved by the Engineer. The Contractor shall clean off the scarified surface thoroughly by power brooming or other approved methods prior to proceeding. The broomed surface shall then be thoroughly moistened over its entire surface before the next layer of soil-cement is placed.

Soil-cement placement operations may commence when the air temperature is not less 40° F and a rising temperature is expected for the work period. Soil-cement shall not be placed on a frozen foundation, or if the soil to be processed is frozen, or if weather conditions are such that the material being processed cannot be

completely compacted and protected before the onset of damaging weather (such as overnight lows below 40° F, cold fronts, rainstorms, etc.). The use of accelerators or antifreeze compounds will not be allowed, unless otherwise specified. The temperature of fresh soil-cement shall not be allowed to drop below 32° F for a period of seven (7) days after placement. If temperatures are expected to be below 45° F, the Contractor's method for protection shall be approved by the Engineer prior to placement of any soil-cement.

When the mean air temperature does not exceed 90° F, the moisture content at the time of compaction shall be within the range specified. When the mean air temperature exceeds 90° F. or conditions promoting rapid drying of the soil-cement mixture exist, the moisture content of the mixture may be increased up to two (2) percentage points above optimum, unless otherwise specified. Any increase in moisture content shall be less than the quantity which will cause the soil-cement to become unstable during the compaction and finishing operations.

9. COMPACTION

- a. Equipment - Compaction equipment used shall be capable of uniformly compacting the soil-cement mixture to the specified density. Compaction equipment shall not have tamping feet or projections that penetrate to previously compacted layers. Compaction with only the wheels of the hauling equipment shall not be an acceptable method of compaction.
- b. Compaction Requirements - Soil-cement shall be uniformly compacted to a density not less than the minimum density specified. Optimum moisture and maximum density shall be determined by ASTM D 558. Natural Resources Conservation Service Test No. S-6 (USBR Test E-25), Rapid Compaction Control Method as referenced in NEH-19, may be used as equivalent to ASTM D 558.

Compaction shall start as soon as possible after spreading. Elapsed time between the addition of water to the soil-cement mixture and the start of compaction shall not exceed sixty (60) minutes. The elapsed time between addition of water to the soil-cement mixture and completion of compaction shall not exceed ninety (90) minutes.

- c. Other Requirements - If the surface of a layer of soil-cement has been rutted or compacted unduly by hauling or other equipment, the Contractor shall scarify and re-compact such surfaces within two (2) hours of the addition of water to the cement. When required to maintain uniformity of the layer surface, blading in connection with compaction operations shall be employed. If blading is required, raw unmixed soil shall not be bladed onto the mixed soil-cement. When greater than two (2) hours has occurred from the time water was added to the cement, the damaged soil-cement shall be removed in a manner and to the extent approved by the Engineer.

10. CONSTRUCTION JOINTS

At the end of each workday, or when the adjacent placing operation is terminated for a period longer than two (2) hours, a vertical construction joint shall be made along all unfinished edges of the thoroughly compacted soil-cement. Just before placing operations are resumed, the construction joint shall be shaved to remove all dry soil-cement and all curing compound from the joint face.

11. REMOVAL AND REPLACEMENT

The soil-cement installation shall be considered defective and shall be removed and replaced in accordance with these specifications, when any one of the following conditions occur:

- a. Compaction operations are interrupted for any reason prior to the completion of compaction and the soil-cement mixture is left undisturbed for more than thirty (30) minutes.
- b. The soil-cement mixture becomes excessively wet prior to completion of compaction, so that the moisture content exceeds the specified limits.
- c. The compacted soil-cement does not meet the density and moisture requirements; except that when the moisture is lower than required, the soil-cement mixture may be reworked, thoroughly mixed, and compacted within the time limits stated in Section 9 (b), previously.
- d. The finished surface is rough or below grade such that a thin "scab" section would be required to smooth the surface or bring the surface to grade.

12. PROTECTING AND CURING

- a. Moistening Bonding Surfaces - Compacted surfaces of soil-cement that are to receive an overlay of soil-cement or concrete shall be kept moist until placement of the overlay or adjacent layer of soil-cement or concrete. The Contractor will not be required to keep such surfaces moistened for longer than seven (7) days, unless the overlay of soil-cement or concrete is not accomplished within seven (7) days as a result of the Contractor's operations.
- b. Curing Finished Exposed Surfaces

Method 1. Concrete curing compound conforming to ASTM C 309 of the type specified shall be applied at a rate of not less than one (1) gallon per 150 square feet of surface using constantly agitating, pressure spray equipment. It shall form a uniform, continuous, adherent film that shall not check, crack, or peel.

The surfaces of each section of soil-cement to be treated with curing compound shall be moistened with a light spray of water immediately after the section has been compacted. As soon as the surface film of moisture disappears, but while

the surface still has a damp appearance, the curing compound shall be applied. Special care shall be implemented to insure ample coverage with the compound at edges, corners, and around rough spots. After application of the curing compound has been completed and the coating is dry to the touch, any required repair of the soil-cement surfaces shall be performed. All curing compound or other foreign substances shall be removed from the area prior to receiving additional soil-cement to ensure a clean bonding surface. Each repair, after being finished, shall be moistened and coated with curing compound in accordance with the foregoing requirements.

Method 2. Curing moisture shall be maintained by sprinkling, flooding, fog spraying, or covering with continuously moistened canvas, cloth mats, straw, sand, or other approved material. Water and/or covering shall be applied in such a manner that the soil-cement surface is not eroded or otherwise damaged.

Method 3. Waterproof paper or plastic sheeting shall be used to completely cover the soil-cement and prevent moisture loss. Adjoining sheeting shall be overlapped at least one (1) foot and weighted or taped to prevent moisture loss at joints. Sheeting shall be anchored sufficiently to prevent displacement due to wind.

All Methods. The curing process shall be maintained for seven (7) days. Any curing compound that is removed from the surface or damaged within seven (7) days after application shall be repaired immediately. The Contractor shall have all equipment and materials required for curing at the site ready for use before starting soil-cement placement activities.

13. INSPECTION AND TESTING

During the course of the work, the Engineer will perform such quality assurance tests as are required to identify materials; determine compaction characteristics; determine moisture content; and determine density of soil-cement in-place. Tests performed by the Engineer will be used to verify that the soil-cement placed conforms to contract requirements of the specifications and not as a replacement for the Contractor's quality control program.

The Contractor shall conduct all required quality control tests in accordance with the approved Contractor Quality Control Plan to assure that work performed meet contract requirements.

14. MEASUREMENT AND PAYMENT

For items of work for which specific unit prices are established in the contract, the quantity of soil-cement will be measured within the specified limits and computed to the nearest cubic yard by the method of average cross-sectional end areas. The quantity of soil-cement required to fill voids resulting from over-excavation outside the neat lines or pay limits will be included in the measurement for payment where such over-excavation is directed by the Engineer to remove unsuitable foundation

material(s), but only to the extent that the unsuitable condition is not a result of the Contractor's improper construction operations, as determined by the Engineer.

Method 1. Payment for soil-cement will be made at the contract unit price per cubic yard. The payment will constitute full compensation for all labor, materials, equipment, transportation, tools, and all other items necessary and incidental to completion of the work, but not including other items listed for payment elsewhere in the contract.

Method 2. Payment for soil-cement will be made at the contract unit price per cubic yard. The payment will constitute full compensation for all labor, materials, equipment, transportation, tools, and all other items necessary and incidental to completion of the work, but not including furnishing and handling cement or other items listed for payment elsewhere in the contract.

Measurement for payment of cement will be made to the nearest 100 pounds by actual weight. For each load of cement delivered, the Contractor shall furnish to the Engineer a statement-of-delivery ticket showing the weight of the cement in the load. Payment for cement will be made at the contract unit price for furnishing and handling the cement and such payment will constitute full compensation for all materials, labor, equipment, storage, transportation, and all other items necessary and incidental to furnishing and handling the cement. No payment will be made for cement used in wasted soil-cement, cement used in replacement of damaged or defective soil-cement, cement used in extra soil-cement required as a result of over-excavation, and excavations intentionally performed to facilitate operations.

All Methods. The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract, but not listed in the bid schedule, will be included in the payment for items of work to which it is made subsidiary. Such payment, and the items to which they are made subsidiary, are identified in Section 15 of this specification.

CONCRETE FOR MAJOR STRUCTURES

1. APPLICABILITY

Construction Specification 31 is applicable to the types of concrete construction entailed in NRCS operations where high material quality is not negotiable. Supplementary specifications will be required for works of a special nature, such as:

- a. Placing concrete under water.
- b. Concrete exposed to seawater.
- c. Concrete exposed to alkali soils or alkaline water.
- d. High strength concrete using microsilica.
- e. Special finishes; such as, sack rubbed, stone rubbed, treatment with cement-based coatings, etc.

Examples of such specifications and guides are contained in Standard Specifications for Highway Bridges, AASHTO and the ACI Manual of Concrete Practice.

2. MATERIAL SPECIFICATIONS

The following material specifications are complementary to Construction Specification 31:

- a. [Aggregates Specification 522](#)
- b. [Cement Specification 531](#)
- c. [Fly Ash Specification 532](#)
- d. [Blast -Furnace Slag Specification 532](#)
- e. [Air-Entraining Admixtures Specification 533](#)
- f. [Water-Reducing and/or Retarding Admixtures Specification 533](#)
- g. [Plasticizing Admixtures Specification 533](#)
- h. [Accelerating and Water-Reducing and Accelerating Admixtures Specification 533](#)
- i. [Curing Compounds Specification 534.](#)
- j. [Preformed Joint Filler Specification 535](#)
- k. [Sealing Compound for Joints Specification 536](#)

l. [Non-Metallic Waterstops Specification 537](#)

m. [Metal Waterstops Specification 538](#)

n. [Dowels Specification 539](#)

o. [Metal Specification 581](#).

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

a. Complete engineering and structural detail drawings of the structure. (See Section 6, National Engineering Handbook.)

b. Type, size and quality of joint filler, waterstops, and metal plates.

c. Deviations, if any, from the specified concrete temperature ranges in Section 21, CONCRETING IN COLD WEATHER.

d. Specify dowel size, spacing, length, and treatment of moveable dowel ends (plastic sleeve, grease, etc.). Also specify deviations, if any, from dowels specified.

e. Deviations, if any, from specifications requiring:

(1) Placement of slab concrete in a single layer.

(2) Consolidation of concrete with vibrators.

f. Section 3, Concrete Mix Design, Method 1. Specify and/or consider the following items:

(1) Class of concrete.

(2) Type of cement.

(3) If water-cement ratios greater than 0.50 will be allowed, they must be specified in Section 25.

(4) Any deviation from the air content and slump specified in Section 3, Method 1, must be specified in Section 25. (The air content specified in Section 3 may not be reduced for structures where the average annual minimum air temperature is below 20° F.)

(5) Aggregate Data. Specify only the nominal maximum size of coarse aggregate and not the ASTM size designation for coarse aggregates.

If Material Specification 522 does not apply, specify the applicable specification and/or the salient properties for aggregate.

(6) Types of admixtures, if any.

(7) Fly Ash and Slag Considerations. Specify in Section 25 if fly ash or ground blast-furnace slag is required or is not allowed in the design mix as a partial substitute for cement. Specify in Section 25 if the fly ash class is restricted to either Class F or C (ASTM C 618). If there is no mention of fly ash or slag in Section 25, the Contractor has the option to use either fly ash (Class F or C) or slag (any grade) in the design mix under Method 1, Section 3.

- g. Section 3, Concrete Mix Design, Method 2. Specify the material proportions and batch weights for the initial job mix which includes: water-cement ratio; cement type and content/cy; coarse aggregate nominal maximum size and content/cy; fine aggregate content/cy; percent air content required; slump requirements; fly ash class and content/cy, if any; slag grade, and content/cy, if any; and any other admixtures that will be used.
- h. Section 9, Conveying. The hot weather limitations for non-plasticized concrete may be waived by the Engineer if the concrete continues to remain within the allowable slump range and the temperature of the concrete does not exceed 90° F. This is consistent with industry practices but the waiver must be based on the performance of the concrete onsite and the Engineer should exercise caution and judgment when waiving the limitations.
- i. Section 10, Placing. Specify a placement plan when required. Placement plans should be considered only when complex placement and/or control is required or expected or when a high volume of concrete is involved.
- j. Section 16, Removal of Forms, Supports, and Protective Coverings.

Strength Test option. Specify a minimum concrete compressive strength for the form removal of structure member in Section 25. The designer and the government assume the risk of form removal at that designated strength.

Cumulative Time option. Form removal time for this option is based upon the structural live load (the final in service load the member must support) being substantially greater than the structural dead load (load of the member only) and no significant horizontal loads on the member when the forms are removed. If the structural dead load is near to or larger than the structural live load, identify in Section 25 the members that will require longer form removal times (See Footnote 2/ for the Accumulative Form Removal Time table.). For walls and columns where forms may be removed quickly and may be exposed to significant horizontal loads; such as, wind loads, different removal times should be specified or the Strength Test option required (See Footnote 3/ for the Accumulative Form Removal Time table.). ACI 347R, Guide to Formwork for Concrete, Paragraph 3.7.2.3 may be used as a reference for removal times.

- k. Specify the finish in Section 25 if a finish other than that required in Section 17 and 18 is needed; such as, an architectural surface, a special finish, or other

necessary restrictions. USBR Concrete Manual, Chapter VI, Sections 119 and 121 may be used as a reference for different finishes.

- l. Section 22, Concreting in Hot Weather. Extreme conditions for formed concrete is a manner of professional judgment on the part of the Engineer. Extreme conditions for flatwork and slab construction is defined as when the evaporation rate exceeding 0.2 lb/ft²/hr. Another method that may be specified in Section 25 or approved is Figure 11-8, page 135, "Design and Control of Concrete", Thirteenth Edition, Portland Cement Association, 5420 Old Orchard Road, Skokie, IL 60077-1083.
- m. Section 23, Acceptance of Concrete Work.

Concrete Strength. The basic premise for acceptance is the approved job mix is delivered to the structure. Strength test failing to meet the required criteria will occasionally occur even though concrete strength and uniformity are satisfactory. The probabilities of a low strength test result from a job mix meeting the criteria in Section 3 are: A 9 percent chance (1 in 11) that an individual strength test will fall below f'_c , a 1 percent chance (1 in 100) that an individual strength test will fall more than 500 psi below f'_c , and a 1 percent chance that the average of three consecutive strength tests will fall below f'_c .

Allowances should be made for such statistically expected variations in deciding whether the strength level being produced is adequate. The criterion of an individual strength test falling more than 500 psi below f'_c adapts well to small numbers of tests (small concrete volumes) and is the strongest indicator that something is wrong with the concrete mix. Although there is a 1% chance that concrete strength will not meet this criteria, verification of the in-place strength should be required if it does not meet the criteria and the contractor required to take actions to improve the strength test averages. The criterion of the average of three consecutive strength tests being equal to or greater than the f'_c is a good trend indicator and not as critical as the other criterion. An occasional average below f'_c can be tolerated; however, if it occurs two or more consecutive times, consideration should be given to verifying the in-place concrete strength and requiring the contractor to take actions to improve the strength test averages.

Structure Dimensions. Specify acceptable tolerances for the structure if the tolerances shown under Structure Dimensions affect the function, strength, or appearance of the structure.

4. DISCUSSION OF METHODS

- a. Section 3, Concrete Mix Design

- (1) Method 1 is intended for use when strength is to be used as one of the criteria for acceptance of the concrete and the Contractor is to be responsible for the mix.

(2) Method 2 is intended for use when the Engineer is to be responsible for and prescribe the concrete mix and strength will not govern acceptance from the Contractor.

b. Section 13, Construction Joints

(1) Method 1 is intended for use in circumstances where maximum bond between old and new concrete is desired. When such joint treatment is specified, it is permissible to design horizontal construction joints as flat plane surfaces without keyways or metal plates. Method 1 is preferred for all structures that are continuously or intermittently exposed to water.

(2) Method 2 is intended for use in circumstances where bond between old and new concrete is not a critical element.

c. Section 24, Measurement and Payment

(1) Method 1 is intended for use with Method 1 in Section 3, when the design and control of the concrete mix is the responsibility of the Contractor (that is, when the compressive strength of the concrete is one of the criteria determining acceptability).

(2) Method 2 is intended for use with Method 2 in Section 3, when the job mix is designed and controlled by the Engineer. A bid item for cement should be included in the specification and the bid schedule.

When specifications are prepared using electronic procedures and all but one method are deleted for use in a contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

31. CONCRETE FOR MAJOR STRUCTURES

1. SCOPE

The work shall consist of furnishing, forming, placing, finishing and curing portland cement concrete as required to build the structures designated in Section 25 of this specification.

2. MATERIALS

Aggregates shall conform to the requirements of Section 25 and Material Specification 522 unless otherwise specified.

Portland cement shall conform to the requirements of Material Specification 531 for the specified type. One brand only of any type of cement shall be used in any single structure as defined in Section 25.

Fly ash shall conform to the requirements of Material Specification 532.

Blast-furnace slag used as a partial substitution of portland cement in concrete shall conform to the requirements of Material Specification 532.

Air-entraining admixtures shall conform to the requirements of Material Specification 533. If air-entraining cement is used, any additional air-entraining admixture shall be of the same type as that in the cement.

Plasticizing admixtures shall conform to the requirements of Material Specification 533.

Water-reducing and/or retarding admixtures shall conform to the requirements of Material Specification 533.

Accelerating and water-reducing and accelerating admixtures, if specified in Section 25, shall conform to the requirements of Material Specification 533.

Curing compound shall conform to the requirements of Material Specification 534.

Preformed expansion joint filler shall conform to the requirements of Material Specification 535.

Sealing compound for joints shall conform to the requirements of Material Specification 536.

Waterstops shall conform to the requirements of Material Specifications 537 and 538 for the specified kinds.

Dowels shall be a plain round steel bar conforming to the requirements of Material Specification 539.

Metal plates shall conform to the requirements of Material Specification 581 for structural quality or commercial or merchant quality steel. Structural quality shall be used only if specifically designated in the drawings or specifications.

Water used in mixing and curing concrete shall be clean and free from injurious amounts of oil, salt, acid, alkali, organic matter or other deleterious substances.

3. CONCRETE MIX DESIGN

Method 1

Responsibilities. The Contractor shall be responsible for the design and proportioning of the concrete. Job mixes shall be prepared to meet the quality, consistency and strength of concrete specified.

Submittals. At least 15 calendar days prior to the placement of any concrete the Contractor shall provide the Engineer with full documentation to support each job mix and any admixtures to be used in the work. The Contractor shall furnish test results to the Engineer for each admixture showing that it meets the requirements of Material Specification 533. Job mixes will be reviewed and accepted or rejected by the Engineer within 8 calendar days following the date of submittal. After a job mix has been accepted, neither the source, character, gradation of the aggregates nor the type or brand of cement or admixtures shall be changed without prior notice to the Engineer. Revisions or changes in a job mix, which are determined to be significant by the Engineer, shall follow the same submittal and acceptance process as for initial job mix.

Design Criteria.

The class of concrete shall be as specified in Section 25 and in accordance with the following specified compressive strength.

<u>Class of Concrete</u>	<u>Specified Compressive Strength (f'_c) at 28 days, (psi)</u>
5000	5000
4000	4000
3000	3000
2500	2500

Maximum water-cement ratio shall be 0.50, unless otherwise specified.

Unless otherwise specified the air content (by volume) of the concrete at the time of placement shall be:

<u>Maximum Size Aggregate</u>	<u>Air Content (%)</u>
3/8 inch to 1 inch	5 to 7
Over 1 inch	4 to 6

The consistency of all concrete shall allow it to be placed without segregation or excessive laitance. Unless otherwise specified, the slump shall be:

<u>Type of Structural Section</u>	<u>Slump (inches)</u>
Massive sections, pavements, footings	2 ± 1
Heavy beams, thick slabs, thick walls (over 12 in.)	3 ± 1
Columns, light beams, thin slabs, thin walls (12 in. or less)	4 ± 1

Superplasticized concrete shall be a concrete mix containing either a water-reducing, high range admixture (ASTM C 494, Type F or G) at a dosage rate that reduces the quantity of water required to produce a concrete mix within the above slump range by 12% or more, or a plasticizing admixture (ASTM C 1017) at a dosage rate required to produce an increase in the slump of at least 2 inches more than that specified above.

Water-reducing admixtures (ASTM C 494) shall not be used to increase the slump of the concrete mix to a slump greater than the slump requirements specified above.

A plasticizing admixture (ASTM C 1017) may be added to an approved job mix without resubmittal and reapproval of the job mix if the following requirements are met:

- a. The plasticizing admixture shall be introduced into the concrete mix as specified by the manufacturer and be compatible with other admixtures in the job mix.
- b. The water content shall be equal to or less than that required in the job mix without the admixture.
- c. The cement content shall be the same as that required in the job mix without the admixture.
- d. The air content shall be within the specified range.
- e. The slump shall not exceed 7-1/2 inches unless the Contractor can demonstrate prior to placement that the job mix can be placed without segregation or excessive laitance at a slump between 7-1/2 inches and 9 inches. The concrete shall retain the increased slump for not less than 30 minutes.

- f. If a plasticizing admixture is added at the job site, the slump of the concrete prior to the addition of the admixture shall not exceed the slump specified above for concrete that does not contain a plasticizing admixture.

Calcium chloride or other corrosive accelerators shall not be used, unless otherwise specified.

Fly ash may be used as a partial substitution for portland cement in an amount not greater than 25 percent (by weight) of cement in the concrete mix, unless otherwise specified.

Ground granulated blast-furnace slag may be used as a partial substitution for portland cement in amounts between 25 to 70 percent (by weight) of cement in the concrete mix, unless otherwise specified.

Job Mix Criteria .

Proportioning of concrete for job mixes shall be based on either the standard deviation computed from compressive strength tests of previous batch records, or established by laboratory trial mixes. A compressive strength test is the average of the compressive strengths of two standard cured cylinders prepared and tested in accordance with Section 4, unless otherwise specified.

- a. For a job mix based upon the standard deviation computed from compressive strength tests of previous batch records, the previous batches shall represent similar materials and conditions to those expected for the job mix and have a strength within 1000 psi of the specified compressive strength (f'_c) at 28 days for the class of concrete specified. The Contractor shall provide to the Engineer copies of the facility's previous batching records that show the compressive strength results and the batch mix design used.
- b. For a job mix based upon a laboratory trial mix, the trial mix shall contain the actual materials to be used in the final job mix, have a slump within 0.75 inches of the maximum allowable slump, and have an air content within 0.5% of the maximum allowable air content. The Contractor shall provide the Engineer with copies of the actual compressive strength test records for the trial mix from the testing facility performing the test.
- c. The trial job mix or previous batch records shall include the water-reducing admixture when a water-reducing admixture is used in a concrete mix specifically to improve the physical properties of the hardened concrete or change portions of the mix components.
- d. In meeting strength requirements, the selected job mix proportions must produce an average strength, f_{cr} , exceeding the specified compressive strength, f'_c , by the amount specified below.

n	s₃₀	f_{cr}
>30	1.00 s	The larger of these two equations: f_c + 1.34 s₃₀ f_c + 2.33 s₃₀ - 500
25	1.03 s	
20	1.08 s	
15	1.16 s	
<15		f_c + 1000 for f_c < 3000 f_c + 1200 for f_c ≤ 5000 f_c + 1400 for f_c > 5000

where **n** = number of consecutive compressive strength tests,
s₃₀ = standard deviation adjusted to 30 tests, psi,
f_{cr} = required average compressive strength, psi,
f_c = specified compressive strength of concrete, psi,
s = standard deviation, psi, computed as,
s = { [sum (**X_i**-**X_a**)² / [**n**-1] }^{1/2}
where **X_i** = individual strength test result, psi, and
X_a = average of n strength test results, psi.

Method 2

Responsibilities. The Engineer will be responsible for the design and proportioning of the job mix. The initial job mix will be as specified in Section 25. The Engineer may adjust the initial job mix proportions to establish the designated job mix. The Engineer will provide the Contractor with a copy of each job mix as soon as the materials and proportions have been determined. After the job mix has been designated, neither the source, character or gradation of the aggregates nor the type or brand of cement or admixtures shall be changed without prior approval of the Engineer. During the course of the work, the Engineer may adjust the job mix proportions and batch weights whenever necessary to meet special job conditions.

The Contractor, for each class of concrete, shall be responsible for:

- a. Taking the following actions and furnish the Engineer with the below information at least 35 calendar days prior to any placement of concrete, unless otherwise designated:
 - (1) Select the source of aggregates and sample and test the gradations of aggregates available;
 - (2) Select the brand and type of cement;
 - (3) Select the brand of admixtures and obtain manufacturer's test data and recommendation of use;

- (4) Identify the concrete production facility, the type of mixer, and the mixing methods that will be used; and
 - (5) Provide from the concrete production facility consecutive compressive strength test records and batching records for concrete mixes that have materials, proportions, and compressive strengths within 1000 psi of the proposed design mix.
- b. Batching at least 3 cubic yards of the initial job mix, in the presence of the Engineer, for testing and evaluation not less than 30 calendar days prior to any placement of concrete.

4. INSPECTING AND TESTING

During the course of the work, the Engineer will perform quality assurance testing as required to assure the concrete meets the contract requirements. The Engineer shall have free entry to the plant and equipment furnishing concrete under the contract. Proper facilities shall be provided for the Engineer to inspect materials, equipment and processes, and to obtain samples of the concrete. All tests and inspections will be conducted so as not to interfere unnecessarily with the manufacture, delivery, and placement of the concrete.

Any portion of a batch may be tested by the Engineer for any of the purposes below. Samples taken for testing shall be representative of that portion of the batch.

- a. Determining uniformity of the batch.
- b. Checking compliance with requirements for slump and air content when the batch is discharged over an extended period of time.
- c. Checking compliance of the concrete with the specifications when the whole amount being placed in a small structure, or a distinct portion of a larger structure, is less than full batch.

If concrete is conveyed to the placement location by pumping or conveyor belts, the samples shall be collected at the discharge end.

When a plasticizing admixture is added to the concrete mix at the job site, slump tests will be made both prior to the addition of the admixture to the concrete mix and after the admixture has been incorporated into the concrete mix.

The tests on concrete will be performed by the following methods indicated, unless otherwise specified:

Type of Test	Test Method (ASTM Designation)
Sampling	C 172
Slump Test	C 143
Air Content	C 231 or C 173
Compression Test Specimens	C 31 or C 42
Compressive Strength Testing	C 39
Unit Weight	C 138
Temperature	C 1064

A strength test for concrete shall be the average of two standard cured concrete cylinders prepared in accordance with ASTM C 31 from the same sample of concrete and tested in accordance with ASTM C 39 at 28 days, unless otherwise specified. If one cylinder shows manifest evidence of improper sampling, molding, curing or testing, it shall be discarded and the strength of the remaining cylinder shall then be considered the compressive strength of the concrete. Should both cylinders show such defects, the entire test shall be discarded.

If both cylinders are discarded or in-place concrete which was not sampled is in question, the in-place concrete may be sampled by coring in accordance with ASTM C 42. For core tests, the below requirements shall be followed:

- a. At least three representative cores shall be taken from each area of concrete in question. If one or more of the cores shows signs of being damaged prior to testing, it shall be replaced by a new one.
- b. Test cores shall be prepared for testing in accordance with moisture conditioning in ASTM C 42, unless the Engineer determines that the concrete in the structure will be dry under service conditions. If the concrete is determined to be dry under service conditions, the cores shall be air dried (temperature 60° to 80° F and relative humidity less than 60%) for 7 days before testing and shall be tested dry.

5. HANDLING AND MEASUREMENT OF MATERIALS

Aggregates shall be stored or stockpiled in such a manner that separation of coarse and fine particles of each size will be avoided and that various sizes will not become intermixed before proportioning. Methods of handling and transporting aggregates shall be such as to avoid contamination, excessive breakage, segregation, degradation, or intermingling of various sizes.

Unless otherwise specified, scales shall be beam type or springless dial type. They shall be accurate when static load tested to $\pm 0.4\%$ of the total capacity of the scales. All exposed fulcrums, clevises and similar working parts of scales shall be kept clean.

Measuring tanks for mixing water shall be of adequate capacity to furnish the maximum amount of mixing water required per batch. Tanks shall be equipped with

outside taps and valves to verify their calibration unless other means are provided for readily and accurately determining the amount of water in the tank.

The quantities of each component of the concrete mix shall be measured by the following methods and to the accuracy indicated below:

Cement, Fly Ash, Slag. Cement, except as otherwise specifically permitted, shall be measured by weight or in bags which have the weight plainly marked on the bag. When cement, fly ash, and slag are supplied in bulk and are measured by weight, they shall be weighed on a scale separate from that used for other materials, and in a hopper entirely free and independent of the hopper used for weighing the aggregate. When fly ash or slag is used in the job mix, the cement and the fly ash or slag may be weighed separately, or cumulatively by weighing the cement first and then adding the fly ash or slag to arrive at the composite weight. The weight of the cement and the combined weight of the cement and fly ash or slag shall be $\pm 1\%$ of the required weight of the cementitious materials. When cement is measured in bags, no fraction of a bag shall be used unless weighed.

Aggregates shall be measured by weight, unless otherwise specifically permitted. Mix proportions shall be based on saturated, surface-dry weights. The batch weight of each aggregate shall be the required saturated, surface-dry weight corrected by the weight of surface moisture it contains. The weight of each of the specified aggregates shall be $\pm 2\%$ of the required weight.

Mixing water shall consist of water added to the batch, ice added to the batch, water occurring as surface moisture on the aggregates, and water introduced in the form of admixtures. The added water shall be measured by weight or volume to an accuracy of 1% of the required total mixing water. Added ice shall be measured by weight. Wash water shall not be used as a portion of the mixing water for succeeding batches.

Admixtures. Dry admixtures shall be measured by weight. Paste or liquid admixtures shall be measured by weight or volume. The admixtures shall be $\pm 3\%$ of the required weight or volume for each specific admixture.

6. MIXERS AND MIXING

Mixers are either stationary parts of a central mixing plant or portable equipment; such as, revolving drum truck mixers and volumetric batching/continuous mixing truck mixers. Mixers shall be capable of thoroughly mixing the concrete ingredients into a uniform mass within the specified mixing time and of discharging the mix without segregation. Each mixer or agitator shall bear a manufacturer's rating plate indicating the gross volume of the drum, the capacity of the drum or container in terms of the volume of mixed concrete, and the minimum and maximum mixing speeds of rotation of the drum, blades, or paddles. When the truck mixer is used for truck mixed concrete as described in Section 6,a,(2) or for shrink mixed concrete as

described in Section 6,a,(3), the capacity of the drum or container in terms of the volume of mixed concrete shall not exceed 63% of the gross volume of the drum. When the truck mixer is used to transport central-mixed concrete as described in Section 6,a,(1), the capacity of the drum or container in terms of the volume of mixed concrete shall not exceed 80% of the gross volume of the drum. The mixer shall be operated in accordance with these recommendations.

Concrete shall be uniform and thoroughly mixed when delivered to the forms in a freshly mixed and unhardened state. Variations in slump of more than one (1) inch within a batch will be considered evidence of inadequate mixing and shall be corrected by changing batching procedures, increasing mixing time, changing mixers or other means. Mixing time shall be within the limits specified below unless the Contractor demonstrates by mixer performance tests that adequate uniformity is obtained by different times of mixing.

No mixing water in excess of the amount called for by the job mix shall be added to the concrete during mixing or hauling or after arrival at the delivery point. Water to compensate for up to a one (1) inch loss in slump may be added, not to exceed the design maximum water cement ratio. Withholding some of the mixing water until the concrete arrives on the job, then adding the remaining water and turning the mixer 30 revolutions at mixing speed will be allowed to overcome transporting conditions. When loss of slump or workability cannot be offset by these measures, complete mixing shall be performed by on-site batching and mixing, or by using a combination of centrally batching and transporting materials to the site and adding remainder of materials onsite.

Concrete may be furnished by (a) ready-mix methods, (b) by volumetric batching and continuous mixing at the site, or (c) by batch mixing at the site.

- a. Ready-Mixed Concrete. Ready-mixed concrete shall be mixed, transported, and placed in a freshly mixed and unhardened state.

The Contractor shall furnish the Engineer a batch ticket showing amount of concrete in cubic yards; the time of loading; the time the load was discharged; the revolution counter reading at the time of loading and discharge; and the type and actual quantity of each material, including all admixtures, used in each batch of concrete.

Truck mixers and truck agitators shall be equipped with revolution counters by which the number of revolutions of the drum or blades may be readily verified.

Ready-mixed concrete shall be mixed and delivered by one of the following methods:

- (1) **Central-Mixed Concrete**. Central-mixed concrete is mixed completely in a stationary mixer and transported to the point of delivery either in a truck agitator, a truck mixer operating at agitating speed, or nonagitating equipment.

When a truck agitator or a truck mixer is used as an agitator and transports concrete that has been completely mixed in a stationary mixer, mixing during transportation shall be at the speed designated by the manufacturer of the equipment as agitating speed. When concrete is transported in a truck mixer or truck agitator, the volume of the mixed concrete shall not exceed 80% of the gross volume of the drum. The total number of revolutions of the truck mixer or truck agitator shall not exceed 200 before discharge of the concrete, unless otherwise specified.

The use of nonagitating equipment to transport concrete to the site of the work will be permitted only if the consistency and uniformity of the concrete as discharged at the point of delivery meet the requirements of this specification. Bodies of nonagitating hauling equipment shall be so constructed that leakage of the concrete mix, or any part thereof will not occur. Concrete hauled in open-top vehicles shall be protected from rain, and from more than 20 minutes exposure to the sun and wind when the air temperature is above 75° F.

(2) **Truck-Mixed Concrete.** Truck-mixed concrete is completely mixed in a truck mixer. The total volume of all ingredients to be mixed in a revolving drum truck mixer shall not exceed 63% of the gross volume of the drum. The concrete ingredients shall be mixed between 70 and 100 revolutions of the drum or blades at the speed designated by the manufacturer as mixing speed. Mixing in excess of 100 revolutions shall be at the speed designated by the manufacturer of the equipment as agitating speed. The total number of revolutions shall not exceed 300 before discharge of the concrete, unless otherwise specified.

(3) **Shrink-Mixed Concrete.** Shrink-mixed concrete is partially mixed at a central plant and the mixing is completed in a truck mixer, the mixing time in the central plant mixer shall be the minimum required to intermingle the ingredients. The volume of the mixed concrete in a truck mixer shall not exceed 63% of the gross volume of the truck drum. The mixing shall be completed in a truck mixer. The number of revolutions of the truck mixer drum or blades shall be between 50 and 100 revolutions at the speed designated by the manufacturer as mixing speed. Mixing in excess of 100 revolutions shall be at the speed designated by the manufacturer of the equipment as agitating speed. The total number of revolutions shall not exceed 300 before discharge of the concrete, unless otherwise specified.

b. Volumetric batching and continuous mixing at the site (Commonly referred to as mobile concrete mixers). Unless otherwise specified, volumetric batching and continuous mixing at the construction site will be permitted. The batching and mixing equipment shall conform to the requirements of ASTM C 685 and shall be demonstrated prior to placement of concrete, by tests with the job mix, to produce concrete meeting the specified proportioning and uniformity

requirements. Concrete made by this method shall be produced, inspected, and documented in conformance with Sections 6, 7, 8, 13, and 14 of ASTM C 685.

- c. Batch mixing at the site. This method of batching and mixing concrete shall be either (a) by batching and mixing all materials onsite by the use of paving mixers or stationary construction mixers, or (b) by using a combination of centrally batching a portion of the mix, transporting it to the site, and adding the remainder of materials and mixing onsite.

Paving mixers or stationary construction mixers and associated transport vehicles shall be in accordance with recommended practices for central-mixed concrete above. The time for mixing a batch of concrete in the mixer drum shall be according to manufacturer's recommendations but not less than 1 minute plus 1/4 minute for each cubic yard of concrete being mixed (8 cy batch = 3 minutes).

When a combination of centrally batching and transporting materials to the site and adding remainder of materials onsite is used, the Contractor shall prepare a written plan detailing how the batching and mixing of the concrete materials will be accomplished and controlled. This written batching and mixing plan shall be submitted to the Engineer for review and approval not less than 10 working days prior to the placement of concrete. The volume of the mixed concrete in a truck mixer shall not exceed 63% of the gross volume of the drum.

The Contractor shall furnish the Engineer for each batch of fresh concrete a batching ticket showing: the type, brand and amount of cement; the type, name, and amount of each admixture; total water added to the batch which includes free water on the aggregate; maximum size of aggregate; the type and dry weight of fine aggregate; the type and dry weight of coarse aggregate; the time of loading (the time that water was introduced to the cement); and the time the load was discharged.

7. FORMS

Forms shall be of good quality wood, plywood, steel or other approved material and shall be mortar tight. The forms and associated falsework shall be substantial and unyielding and shall be constructed so that the finished concrete will conform to the specified dimensions and contours. Form surfaces shall be smooth and free from holes, dents, sags or other irregularities and maintained in this condition throughout the work. Forms shall be coated with a nonstaining form release agent before being set into place. Acceptable tolerances for formed structure members are specified in Section 23.

When a superplasticized concrete mix is used, forms shall be coated, according to the manufacturer's recommendations, with a form release agent that is specifically formulated for plasticized concrete. Forms shall be designed to withstand the increased pressures of the superplasticized concrete and the increase impact forces resulting from larger drop heights used in placing the superplasticized concrete.

Metal ties or anchorages which will be embedded in the concrete shall be equipped with cones, she-bolts or other devices that permit their removal to a depth of at least one inch without injury to the concrete. Ties designed to break off below the surface of the concrete shall not be used without cones. If approved fiberglass or plastic form ties are used, the tie ends shall be cut flush with the finished concrete and ground smooth.

All edges that will be exposed shall be chamfered, unless finished with molding tools as specified in Section 18.

8. PREPARATION OF FORMS AND SUBGRADE

Prior to placement of concrete, the forms, embedments, and subgrade shall be free of chips, sawdust, debris, water, ice, snow, extraneous oil, mortar, or other harmful substances or coatings. Any form release agent on the reinforcing steel or other surfaces required to be bonded to the concrete shall be removed.

Rock surfaces shall be cleaned by high pressure air-water cutting, sandblasting or wire brush scrubbing, as necessary, and shall be wetted immediately prior to placement of concrete. Earth surfaces shall be firm and damp. Placement of concrete on mud, dried earth, noncompacted fill or frozen subgrade will not be permitted. All ice, snow and frost shall be removed and the temperature of all surfaces, including the reinforcing steel and other steel inclusions, to be in contact with the new concrete shall be no colder than 40° F.

Items to be embedded in the concrete shall be positioned accurately and anchored firmly.

Weepholes in walls or slabs shall be formed with nonferrous materials.

9. CONVEYING

Concrete shall be delivered to the site and discharged completely into the forms within 1-1/2 hours or before the drum of truck has revolved a total of 300 revolutions, whichever comes first, after the introduction of the mixing water to the cement and aggregates or the introduction of the cement to the aggregates. In hot weather or under conditions contributing to quick stiffening of the concrete, or when the temperature of the concrete is 85° F or above, the time between the introduction of the cement to the aggregates and discharge shall not exceed 45 minutes.

Superplasticized concrete can be conveyed and placed when the temperature of the concrete is below 95° F and the slump of the concrete remains within the allowable slump range.

The Engineer will allow an appropriate extension of time when the setting time of the concrete is increased a corresponding amount by the addition of an approved admixture. In any case, concrete shall be conveyed from the mixer to the forms as

rapidly as practicable, by methods that will prevent segregation of the aggregates or loss of mortar.

10. PLACING

Concrete shall not be placed until the subgrade, forms, steel reinforcement, and other embedments have been inspected and approved by the Engineer. For walls and columns, subsequent higher placements of concrete shall not be placed until the concrete below the new placement has gained sufficient strength to support the concrete dead load and any superimposed loads without distress. Placement sequences and timing shall consider form removal timing covered in Section 16.

If a placement plan is required in Section 25, concrete shall not be placed until the placement plan has been reviewed and approved by the Engineer.

The Contractor shall have all equipment and materials required for curing available at the site ready for use before placement of concrete begins.

Concrete shall be placed only in the presence of the Engineer. The Contractor shall give reasonable notice to the Engineer prior to each placement. Such notice shall be far enough in advance to give the Engineer adequate time to assure that the subgrade, forms, steel reinforcement and other preparations comply with specifications. Other preparations include, but are not limited to, the concrete batching plant, mixing and delivery equipment and system, placing and finishing equipment and system, schedule of work, work force and heating or cooling facilities as applicable. All deficiencies are to be corrected before concrete is delivered for placing.

Concrete shall be placed and consolidated in a manner that will prevent segregation of the mix components. The concrete shall be deposited as closely as possible to its final position in the forms and shall be worked into the corners and angles of the forms and around all reinforcement and embedded items in a manner to prevent segregation of aggregates or excessive laitance. The depositing of concrete shall be regulated so that the concrete can be consolidated with a minimum of lateral movement. Concrete placed against sloping surfaces shall start at the lowest elevation and work upwards to the highest elevation.

Concrete other than architectural concrete shall not be dropped more than 5 feet vertically unless suitable equipment is used to prevent segregation. Architectural concrete shall not be dropped more than 3 feet vertically unless suitable equipment is used to prevent segregation. When a superplasticized concrete mix is used, concrete other than architectural concrete shall not be dropped more than 12 feet vertically and architectural concrete shall not be dropped more than 10 feet vertically unless suitable equipment is used to prevent segregation.

11. LAYERS

Slab concrete shall be placed to design thickness in one continuous layer, unless otherwise specified.

Formed concrete shall be placed in horizontal layers not more than 20 inches deep. When a superplasticized concrete mix is used, formed concrete may be placed in horizontal layers not more than 5 feet deep.

Successive layers of fresh concrete between construction joints shall be placed at a rate fast enough that the preceding layer is still plastic and can be easily mixed with the fresh concrete such that seams ("cold joints") or plane of weakness will not occur. If the surface of a previously placed layer of concrete has taken a set to the degree that it will not flow and mix with the succeeding layer when vibrated, the Contractor shall discontinue placing concrete and shall make a construction joint according to the procedure specified in Section 13. If placing is discontinued when a layer is incomplete, the ends of the incomplete layer shall be formed by a vertical bulkhead.

12. CONSOLIDATING

All concrete shall be consolidated with internal type mechanical vibrators capable of transmitting vibration to the concrete at frequencies not less than 8000 impulses per minute, unless otherwise specified or approved prior to placement. Vibration shall be supplemented by spading, rodding, and hand tamping, as necessary to insure smooth and dense concrete along form surfaces, in corners, and around embedded items. The Contractor shall provide a sufficient number of vibrators to properly consolidate the concrete immediately after it is placed. A sufficient number of standby vibrators shall be kept onsite during the placement of concrete.

Vibration shall compact the concrete and bring it into intimate contact with the forms, reinforcing steel, and other embedded items while removing voids and pockets of entrapped air. The location, insertion, duration, and removal of the vibrators shall be such that maximum consolidation of the concrete is achieved without causing segregation of the mortar and coarse aggregate or causing water or cement paste to flush to the surface. Vibration shall be applied to the freshly deposited concrete by rapidly inserting the vibrator and slowly in an up and down motion removing the vibrator at points uniformly spaced at not more than 1-1/2 times the radius of the area visibly effected by vibration. Generally, rapidly inserting the vibrator and removing the vibrator with an up and down motion at 5 to 10 seconds per foot on 14 inch spacings or less. The area visibly effected by the vibrator shall overlap the adjacent, just vibrated area. The vibrator shall extend vertically into the previously placed layer of fresh concrete by at least 6 inches, at all points, to insure effective bond between layers. In thin slabs, the vibrator(s) should be sloped toward the horizontal to allow operations in a fully embedded position.

Vibration shall not be applied directly to the reinforcement steel, the forms, or other embedded items, unless otherwise specified. Vibration shall not be applied to concrete that has hardened to the degree that it does not become plastic when

vibrated. If surface vibrators are used, surface vibrators may contact forms when consolidating thin slabs.

The use of vibrators to transport concrete in the forms or conveying equipment will not be permitted.

Surface vibrators may be used to consolidate thin slabs 8 inches and less in thickness. For slabs greater than 8 inches in thickness, the slab shall be consolidated with internal vibration and may be augmented through use of surface vibrators; such as, vibrating screeds, plate or grid vibratory tampers, or vibratory roller screeds. If concrete is to be consolidated using surface vibration methods, the Contractor shall detail in writing how this work is to be performed, including equipment selection and specifications, to the Engineer for review and approval not less than 30 calendar days prior to placing concrete by this method.

13. CONSTRUCTION JOINTS

Construction joints shall be made at the locations shown on the drawings, unless otherwise specified or approved by the Engineer. If construction joints are needed which are not shown on the drawings, they shall be placed in locations approved by the Engineer.

Where a feather edge would be produced at a construction joint, as in the top surface of a sloping wall, an insert form shall be used so that the resulting edge thickness on either side of the joint is not less than twice the maximum aggregate diameter used in the concrete mix.

Nonvertical construction joints in structural elements; such as, walls and columns, shall be consolidated and screeded to grade, unless otherwise specified. Construction joints shall be covered and wet cured for 7 days or until concrete placement resumes, unless otherwise specified.

Steel tying and form construction adjacent to concrete in-place shall not be started until the concrete has cured at least 12 hours. Before new concrete is deposited on or against concrete that has hardened, the forms shall be retightened. New concrete shall not be placed until the hardened concrete has cured at least 12 hours.

Method 1 Surfaces of construction joints shall be cleaned of all unsatisfactory concrete, laitance, coatings, stains or debris by either sandblasting after the concrete has gained sufficient strength to resist excessive cutting, or high pressure air-water cutting as soon as the concrete has hardened sufficiently to prevent the jet from displacing the coarse aggregates, or both. The surface of the concrete in-place shall be cut to expose clean, sound aggregate but not so deep as to undercut the edges of larger particles of the aggregate. After cutting, the surface shall be thoroughly washed to remove all loose material. If the surface is congested by reinforcing steel, is relatively inaccessible, has cured beyond the ability to cut with air-water blasting, or it is considered undesirable to disturb the concrete before it is

hardened, cleaning of the joint by air or water jets will not be permitted and the sandblasting method will be required after the concrete has hardened.

Immediately before new concrete is placed, all construction joints shall be wetted and standing water removed.

Method 2 Surfaces of construction joints shall be cleaned of all unsatisfactory concrete, laitance, coatings, stains, or debris by washing and scrubbing with a wire brush or wire broom, or by other means approved by the Engineer. Immediately before new concrete is placed, all construction joints shall be wetted and standing water removed.

14. EXPANSION AND CONTRACTION JOINTS

Expansion and contraction joints shall be made only at locations shown on the drawings.

Exposed concrete edges at expansion and contraction joints shall be carefully tooled or chamfered, and the joints shall be free of mortar and concrete. Joint filler shall be fully exposed for its entire length with clean and true edges.

When open joints or weakened plane "dummy" joints are specified, joints formed in fresh concrete shall be constructed by the insertion and subsequent removal of a wood strip, metal plate or other suitable template in such a manner that the corners of the concrete will not be chipped or broken. The edges of the fresh concrete at the joints shall be finished with an edging tool prior to removal of the joint strips. Open joints or weakened plane "dummy" joints may also be saw-cut joints conforming to the depth and extent specified.

Preformed expansion joint filler shall be held firmly in the correct position as the concrete is placed.

15. WATERSTOPS

Waterstops shall be held firmly in the correct position as the concrete is placed. Joints in metal waterstops shall be brazed or welded. Joints in rubber or plastic waterstops shall be cemented, welded or vulcanized as recommended by the manufacturer. Joints shall be watertight and of a strength equivalent to that specified in Material Specification [537](#). Intersecting waterstop joints shall be prefabricated and supplied by the same manufacturer providing the waterstop.

16. REMOVAL OF FORMS, SUPPORTS, AND PROTECTIVE COVERINGS

Forms, supports, and protective coverings shall be removed as soon as practical after the concrete has gained sufficient strength to support its own weight and superimposed loads. Removal shall be done in a manner that will not damage the concrete surface nor induce sudden or excessive stresses.

The minimum period from completion of the concrete placement to the removal of the forms shall be based on either Strength Tests or Cumulative Times.

Strength Tests. The strength of the in-place concrete will be determined by testing concrete cylinders specifically cast for this purpose and cured adjacent to the member in accordance with the ASTM C 31 method for determining removal time. Unless otherwise specified, forms supporting the weight of the concrete member may be removed after the concrete strength is 70% of that specified for the Class of concrete. Forms not supporting the weight of the concrete member or other superimposed loads may be removed after the concrete strength has reached the strength specified in Section 25.

Cumulative Time. The total accumulated time, not necessarily continuous, that the air adjacent to the concrete is above 50° F and the specified concrete curing has occurred concurrently will be determined. Forms may be removed after the total accumulated time in the following table:

ACCUMULATED FORM REMOVAL TIMES		
Sides of Slabs or Beams		^{1/} 12 hours
Undersides of Slabs or Beams	Clear Span	^{1/ 2/}
	< 10 ft	4 days
	10 - 20 ft	7 days
	> 20 ft	14 days
Sides of Walls or Columns	Height Above Form	^{1/ 3/ 4/}
	≤ 10 ft	12 hours
	≤ 20 ft	24 hours
	> 20 ft	72 hours

- ^{1/} Table values apply to normal concrete. Values for concrete which contains cements or admixtures that significantly retard or accelerate strength gain will be determined by the Engineer and based on actual design mix data.
- ^{2/} Values apply to members designed to support significant superimposed loads. Values for members designed for only self weight when placed in service shall be 50% greater.
- ^{3/} Values apply to members not subject to significant horizontal loads. Additional time or rebracing will be needed for members subject to significant wind or other horizontal loads.
- ^{4/} Subsequent higher lifts may be placed after 12 hours.

17. FINISHING FORMED SURFACES

All formed concrete surfaces shall be true and even, and shall be free from over-tolerance depressions, holes, projections, bulges, or other defects in the specified surface finish or alignment, unless otherwise specified in Section 25. Depressions are measured as the distance from the bottom of a 5 foot long template or straight edge.

Surfaces to be backfilled or otherwise concealed when construction is completed shall have the following surface treatment, unless otherwise specified: Repair defective concrete, fill all form tie holes, correct surface depressions deeper than 1 inch, and remove or smooth fins and abrupt projections that exceed 3/4 inch.

Surfaces to be permanently exposed, where other finishes are not specified, shall have the following treatment: Repair defective concrete, fill all form tie holes, remove or smooth all abrupt irregularities greater than 1/4 inch in depth or projection, and treat all depressions and irregularities such that they do not exceed 1/2 inch in depth.

Repair and filling of form bolt and tie holes, and other holes of similar size and depth shall be performed as specified in Section 20.

18. FINISHING UNFORMED SURFACES

All exposed surfaces of the concrete shall be accurately screeded to grade and then float finished, unless otherwise specified. The float finish shall result in a surface that has no irregularities that exceeds 1/4 inch when checked with a template or straight edge that is 10 feet long.

All exposed surfaces of concrete shall be accurately struck off to grade after placement and consolidation are completed. Following strike-off, the surfaces shall be immediately smoothed by darbying or bull floating before any free water has bled to the surface. The concrete shall then be allowed to rest until the bleed water and water sheen has left the surface and the concrete has stiffened to where it will sustain foot pressure with only about 1/4 inch indentation. At this time all joints and edges that will be exposed to view that are not chamfered shall be finished with edging tools. After edging and hand-jointing is complete, all exposed surfaces shall be floated with wood or magnesium floats. The floating should work the concrete no more than necessary to remove screed, edger and jointer marks and produce a compact surface, uniform in texture.

Water shall not be sprinkled or added to the surface of the concrete during the darbying, bull floating, floating, or other finishing operations to facilitate finishing.

19. CURING

Freshly placed concrete shall be cured a minimum of 7 days in accordance with the recommended practices set forth below. A curing process shall be started as soon as the concrete has hardened sufficiently to prevent surface damage. Curing concrete, including exposed surfaces of formed concrete and concrete in forms,

shall be maintained at a satisfactory moisture content for at least 7 days following placement. If forms are removed prior to the end of the 7 day curing period, the interrupted curing process shall be re-established and maintained until a full 7 day curing period is achieved.

A satisfactory moisture condition is: (a) Continuous or frequent application of water or use of a saturated cover material; such as, canvas, cloth, burlap, earth, sand, etc., or (b) Prevention of excessive water loss from the concrete by use of an impermeable coating (curing compound) or covering (plastic, paper, etc.). The application of water or covering shall not erode, mar, or otherwise damage the concrete. Plastic film or paper shall meet the requirements of ASTM C 171. Black covering shall not be used when concreting in hot weather.

Except as otherwise specified in Section 25, curing compound may be used for exposed surfaces or formed surfaces after patching and repair have been completed. Unless otherwise specified, the curing compound shall be white pigmented and conform to ASTM C 309, Type 2, Class A or B. Clear curing compound (Type 1) or clear with fugitive dye (Type 1-D) may be used only when specified in Section 25. Curing compounds shall not be used on surfaces that are to receive additional concrete, paint, tile, or other coatings unless the Contractor demonstrates that the membrane can be satisfactorily removed or can serve as a base for the later application.

Curing compound shall be thoroughly mixed before applying and agitated during application. Except as otherwise specified in Section 25, the compound shall be applied at a pressure of 75 to 100 psi using a continuously agitating pressure sprayer at a uniform rate of not less than one gallon per 175 square feet of surface. Manual hand pump sprayers shall not be used unless otherwise specified. For individual concrete placements or repairs having a surface areas of 400 square feet or less, curing compound may be applied with a soft-bristled brush, paint roller, or hand sprayer. The compound shall form a uniform continuous, adherent film that shall not check, crack or peel and shall be free from pinholes or other imperfections.

All surfaces covered with curing compound shall be continuously protected from damage to the protective film during the required curing period.

Surfaces subjected to heavy rainfall or running water within 3 hours after the compound has been applied, or surfaces damaged by subsequent construction operations during the curing period shall be resprayed in the same manner as for the original application.

Water for curing shall be clean and free from any substances that will cause discoloration of the concrete.

20. CONCRETE PATCHING, REPAIR OR REPLACEMENT

Patching. All form bolts, metal ties, and similar forming restraints shall be removed to a depth of one inch below the surface of the concrete and their cavities repaired

unless otherwise specifically permitted or specified. Small cavities, large air holes, minor honeycombed areas, and other superficial imperfections that require patching to meet the specified finish requirements shall be thoroughly cleaned and filled. Holes left by bolts or straps that pass through the concrete section shall be filled solid with a dense, well-bonded, nonshrink patching material. Dry-pack mortar and replacement concrete shall follow the appropriate procedure detailed in the Repair and Maintenance chapter of the Concrete Manual, Bureau of Reclamation, U.S. Department of the Interior. Proprietary patching materials shall be appropriate for the type of repair, used within the manufacturer's recommended limits, and applied according to the manufacturer's recommendations.

Repair or Replacement. The Contractor shall repair and/or replace concrete that does not meet the requirements of this specification. Prior to starting any repair or replacement work, the Contractor shall prepare a written plan for the repair or replacement. The primary reference for materials and repair methods for the plan shall be the appropriate sections of the Repair and Maintenance chapter of the Concrete Manual, Bureau of Reclamation, U.S. Department of the Interior. The repair plan shall be submitted to the Engineer for review at least ten days prior to any repair or replacement work. Approval of the plan will be authorized in writing by the Contracting Officer.

When proprietary patching materials are proposed in the plan, the manufacturer's data sheets and written recommendations shall be included in the plan.

Repair materials or replacement concrete shall have properties, color, and texture similar to and compatible with the concrete being repaired or replaced. Repair or replacement concrete work shall be performed only when the Engineer is present.

Curing of repaired or replaced concrete shall be started immediately after finish work is completed and as specified in Section 19 or as specified by the manufacturer of proprietary compounds.

21. CONCRETING IN COLD WEATHER

Methods for concreting in cold weather shall be performed when, for more than 3 consecutive days, the following conditions exist: (a) the average daily air temperature at the job site is less than 40° F and (b) the air temperature at the job site is not greater than 50° F for more than one-half of any 24-hour period. The average daily air temperature is the average of the highest and lowest temperatures occurring during the period from midnight to midnight.

Concrete shall be protected against freezing during the first 24 hours after placement whether or not the average weather conditions specified above for cold weather concreting exist.

The following provisions also shall apply, unless otherwise specified:

- a. When the cement is added to the mix, the temperature of the mixing water shall not exceed 140° F nor shall the temperature of the aggregate exceed 150° F.
- b. The temperature of the concrete at the time of placing shall be within the placement temperature range shown below, unless otherwise specified.

<u>Least dimension of Section, inches</u>	<u>Placement Temperature, F</u>
Less than 12	55 - 75
12 to 36	50 - 70
36 to 72	45 - 65
Greater than 72	40 - 60

- c. The minimum temperature of the concrete for the first 72 hours after placement shall not be less than the minimum temperature shown above. Concrete structures shall be immediately protected after concrete placement by methods of covering, housing, insulating, or heating concrete structures that will be sufficient to maintain the minimum temperature adjacent to the concrete surface. If the minimum temperature requirements are not met and the concrete did not freeze, the protection time will be extended a period equal to twice the number of hours the temperature was below the minimum temperature.
- d. Exhaust flue gases from combustion heaters shall be vented to the outside of the enclosure. The heat from heaters and ducts shall be directed in such a manner as to not overheat or dry the concrete in localized areas or to dry exposed concrete surfaces.
- e. At the end of the protection period, the concrete shall be allowed to cool gradually. The maximum decrease at the concrete surface in a 24-hour period shall not exceed 40° F.

22. CONCRETING IN HOT WEATHER

Methods for concreting in hot weather shall be in accordance with the requirements set forth below.

For the purpose of this specification, hot weather is defined as any combination of the following conditions that impair the quality of freshly mixed or hardened concrete by accelerating the rate of moisture loss and rate of cement hydration, or otherwise resulting in detrimental results:

- *** High ambient temperature
- *** High concrete temperature
- *** Low relative humidity
- *** Wind velocity
- *** Solar radiation.

Whenever the above conditions exist or when climatic conditions are such that the temperature of the concrete may reasonably be expected to exceed 90° F at the time of delivery to the work site or during the placement operations, the following provisions shall apply:

- a. The Contractor shall maintain the temperature of the concrete below 90° F during mixing, conveying, and placing.
- b. Exposed concrete surfaces which tend to dry or set too rapidly shall be continuously moistened by means of fog sprays or other means to maintain adequate moisture during the time between placement and finishing. Water shall not be sprinkled or added directly to the surface of the concrete prior to finishing.
- c. Finishing of slabs and other exposed surfaces shall be started as soon as the condition of the concrete allows and shall be completed without delay. Water shall not be sprinkled or added to the surface of the concrete during the darbying, bull floating, floating, or other finishing operations to facilitate finishing.
- d. Formed surfaces shall be kept completely and continuously wet from the time the concrete takes initial set to when the forms are removed. After the forms are removed, the concrete surfaces shall be kept completely and continuously wet for the duration of the curing period or until curing compound is applied in accordance to Section 21.
- e. Exposed and unformed concrete surfaces, especially flat work placed with large areas of surface, shall be kept completely and continuously wet for the duration of the curing period or until curing compound is applied in accordance to Section 19. The concrete shall be protected against thermal shock from rapid cooling (5° F per hour or more than 40° F per 24-hour period) of the concrete by application of curing water or temperature changes during the first 24 hours of the curing period.
- f. When any single or combination of conditions may result in very rapid setting or drying of the concrete, extreme conditions exist. For flat work and slab construction, extreme conditions exist when the evaporation rate exceeding 0.2 lb/ft²/hr.

The Engineer may (1) restrict placement to the most favorable time of the day, (2) restrict the depth of layers to assure coverage of the previous layer while it will still respond readily to vibration, (3) suspend placement until conditions improve, and (4) restrict the removal of forms, repair, and patching to small areas which can be protected with curing compound immediately.

The evaporation rate for flat work and slab construction may be determined by calculating the evaporation rate from a shallow cake pan having a surface area of at least 1 square foot or by other methods approved by the Engineer or designated in Section 25.

23. ACCEPTANCE OF THE CONCRETE WORK

Acceptance of the concrete work will be a cumulative acceptance process based upon progressively meeting the requirements of the specifications and drawings for:

- *** Fresh concrete,
- *** Concrete strength and durability,
- *** Structure dimensions, and
- *** Structure appearance.

Fresh Concrete

Fresh concrete conforming to the mix proportions and quality requirements of the approved job mix and the handling and placement requirements of previous sections will be satisfactory.

Concrete Strength

A strength test is the average of the compressive strengths of two standard cured cylinders prepared and tested in accordance with Section 4, unless otherwise specified. The strength of the hardened concrete will be satisfactory if the following requirements are met:

- a. If Method 1 from Section 3 is specified and the concrete work is less than 75 total cubic yards for the class of concrete specified, the compressive strength of the concrete will be satisfactory if no individual strength test falls more than 500 psi below the specified compressive strength (f'_c) for the respective class of concrete.
- b. If Method 1 from Section 3 is specified and the concrete work is 75 total cubic yards or more for the class of concrete specified, the compressive strength of the concrete will be satisfactory if both of the following requirements are met:
 - (1) No individual strength test falls more than 500 psi below the specified compressive strength (f'_c) for the class of concrete specified.
 - (2) The average of any three consecutive strength tests is not less than the specified compressive strength (f'_c) two or more consecutive times for the class of concrete specified.

The Contractor shall take steps to increase the average of subsequent strength tests when the average of any three consecutive strength tests falls below the specified concrete strength (f'_c).

- c. The Engineer will determine the structural adequacy and evaluate the durability of the in-place concrete when the concrete strength based on the standard cured

concrete cylinders is unsatisfactory. The Engineer will determine the need for additional quality assurance testing.

- d. The Contractor may core the concrete, have the cores tested by a certified testing laboratory at the Contractor's expense, and submit test results to the Engineer for consideration and evaluation of concrete strength adequacy when the concrete strength based on the standard cured concrete cylinders is unsatisfactory.
- e. Sampling and testing concrete by coring shall conform to Section 4. The strength of the concrete based upon concrete cores will be satisfactory if both of the following requirements are met:
 - (1) The average compressive strength of the three cores equal or exceed 85 percent of the specified compressive strength (f'_c).
 - (2) The compressive strength of any individual core does not fall below 75 percent of the specified compressive strength (f'_c).
- f. If Method 2 from Section 3 is specified, the Engineer is responsible for the concrete job mix design and the quality concrete that results from the job mix.

The hardened concrete will be satisfactory if the required batch tickets or other documentation acceptable to the Engineer clearly show that the batch ingredients and weights of each ingredient including all admixtures conforms to the job mix provided by the Engineer. Random periodic inspection of the batching operations may be made by the Engineer to verify that ingredients and ingredient proportions conform to the batching documentation.

If the concrete ingredients, proportions, or admixtures varies from the job mix provided by the Engineer, the concrete may be rejected if, in the judgment of the Engineer, the variance will significantly affect the strength or durability of the concrete or will adversely affect the life expectancy or other components of the structure.

Structure Dimensions and Appearance

The appearance of the concrete shall meet the requirements of Sections 17 and 18.

The dimensions of formed members, unless otherwise specified, will be satisfactory if they conform to the requirements of the specifications, the locations shown on the drawings, and are within acceptable tolerances below:

- a. Variation from plumb for walls and column shall be not more than 0.2% of the wall or column height.
- b. Variation from specified elevations for slabs, floors, or other horizontal members shall be not more than 0.2% of the length of the member in the direction of grade.

- c. Variations in the cross-sectional dimensions of columns and beams and in the thickness of walls and above-grade slabs shall not be more than minus 1/4 inch or plus 1/2 inch from the shown dimensions.

24. MEASUREMENT AND PAYMENT

For items of work for which specific unit prices are established in the contract, concrete will be measured to the neat lines or pay limits shown on the drawings, and the volume of concrete will be computed to the nearest 0.1 cubic yard. No deduction in volume will be made for chamfers, rounded or beveled edges, or for any void or embedded item that is less than five cubic feet in volume. Where concrete is placed against the sides or bottom of an excavation without intervening forms, drainfill, or bedding, the volume of concrete required to fill voids resulting from overexcavation outside the neat lines or pay limits will be included in the measurement for payment where such overexcavation is directed by the Engineer to remove unsuitable foundation material; but only to the extent that the unsuitable condition is not a result of the Contractor's improper construction operations, as determined by the Engineer.

Method 1 Payment for each item of concrete will be made at the contract unit price for that item. The payment for concrete will constitute full compensation for completion of the concrete work, including joint fillers, waterstops, dowels or dowel assemblies and metal plates, but not including reinforcing steel or other items listed for payment elsewhere in the contract.

Method 2 Payment for each item of concrete will be made at the contract unit price for that item. The payment for concrete will constitute full compensation for completion of the concrete work, including joint fillers, waterstops, metal plates, dowels, and other assemblies, but not including furnishing and placing reinforcing steel or furnishing and handling cement or other items listed for payment elsewhere in the contract.

Cement will be measured by dividing the volume of concrete accepted for payment by the yield of the applicable job mix. The yield will be determined by the procedure specified in ASTM C 138. If the amount of cement actually used per batch exceeds the amount in the job mix specified by the Engineer, the measurement will be based on the amount of cement specified by the Engineer for the job mix. Unless otherwise stated in Section 25, a bag of cement will be considered 94 pounds. Payment for each type of cement will be made at the contract unit price for furnishing and handling that type of cement and such payment will constitute full compensation for furnishing and handling the cement.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 25 of this specification.

INSTRUCTIONS FOR THE USE OF CONSTRUCTION SPECIFICATION 32

STRUCTURE CONCRETE

1. APPLICABILITY

Construction Specification 32 is applicable for the installation of low and moderate hazard structures, where the quantity of concrete is generally 75 cubic yards or less per structure, and where the location of the structure will allow economical maintenance or replacement.

2. MATERIAL SPECIFICATIONS

Material Specifications [522](#), [531](#), [532](#), [533](#), [534](#), [535](#), [537](#), and [538](#) are complementary to Construction Specification 32. When local aggregates do not conform to the requirements of Material Specification [522](#) but are known to produce concrete of adequate quality, reference to Interim Standard Material Specification is permissible, or requirements may be stated in the construction details in Section 24.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Class of concrete.
- b. Type, size and quantity of joint filler, waterstop, and any other items to be embedded.
- c. Type of cement.
- d. Specify in Section 24 if fly ash or ground blast furnace slag is required or is not allowed in the design mix as a partial substitute for cement.
- e. Nominal size of coarse aggregate; or specifications for aggregate if Material Specification [522](#) does not apply-
- f. Type of admixtures, if any.
- g. Special slump and air content requirements, if applicable.
- h. If volumetric batching and continuous mixing will not be permitted, include a statement to that effect.
- i. Special type of finish or coating of finished surfaces.
- j. Note in Section 24 any other deviations from the basic specifications.

4. DISCUSSION OF METHODS

a. Section 23, Measurement and Payment

Describe method of measurement and payment if it differs from the methods listed.

CONSTRUCTION SPECIFICATION

32. STRUCTURE CONCRETE

1. SCOPE

The work shall consist of furnishing, forming, placing, finishing, and curing portland cement concrete as required to build the structures described in Section 24 of this specification.

2. MATERIALS

Aggregates shall conform to the requirements of Material Specification 522 unless otherwise specified. The grading of coarse aggregates shall be as specified in Section 24.

Portland cement shall conform to the requirements of Material Specification 531 for the specified type.

Fly ash shall conform to the requirements of Material Specification 532.

Air-entraining admixtures shall conform to the requirements of Material Specification 533. If air-entraining cement is used, any additional air-entraining admixture shall be of the same type as that in the cement.

Water reducing and/or retarding admixtures shall conform to the requirements of Material Specification 533.

Curing compound shall conform to the requirements of Material Specification 534.

Preformed expansion joint filler shall conform to the requirements of Material Specification 535.

Waterstops shall conform to the requirements of Material Specifications 537 and 538 for the specified kinds.

Water used in mixing and curing concrete shall be clean and free from injurious amounts of oil, salt, acid, alkali, organic matter or other deleterious substances.

3. CLASS OF CONCRETE

Concrete for structure concrete shall be classified as follows:

<u>Class of Concrete</u>	<u>Maximum Net Water Content (gallons/bag)</u>	<u>Minimum Cement Content (bags/cu. yd.)</u>
3000M	6	5-1/2
4000M	6	6

4. AIR CONTENT AND CONSISTENCY

Unless otherwise specified, the slump shall be 3 to 5 inches. If air entrainment is specified, the air content by volume shall be 4 to 7 percent of the volume of the concrete. When specified, directed or approved by the Engineer, a water-reducing, set-retarding or other admixture shall be used. High Range Water Reducing Agents (Superplasticizers) may be used to increase workability, reduce water content and control concrete temperature in hot weather. The maximum slump after adding high range water reducing agents shall be 7-1/2 inches.

5. DESIGN OF THE CONCRETE MIX

The proportions of the aggregates shall be such as to produce a concrete mixture that will work readily into the corners and angles of the forms and around reinforcement when consolidated, but will not segregate or exude free water during consolidation.

Fly ash may be used as a partial substitution for portland cement in an amount not greater than 25 percent (by weight) of the cement in the concrete mix, unless otherwise specified.

Prior to placement of concrete, the Contractor shall furnish the Engineer, for approval, a statement of the materials and mix proportions (including admixtures, if any) he intends to use. The statement shall include evidence satisfactory to the Engineer that the materials and proportions will produce concrete conforming to this specification. The materials and proportions so stated shall constitute the "job mix". After a job mix has been approved, neither the source, character or grading of the aggregates nor the type or brand of cement or admixture shall be changed without prior notice to the Engineer. If such changes are necessary, no concrete containing such new or altered materials shall be placed until the Engineer has approved a revised job mix.

6. INSPECTION AND TESTING

The Engineer shall have free entry to the plant and equipment furnishing concrete under the contract. Proper facilities shall be provided for the Engineer to inspect materials, equipment and processes and to obtain samples of the concrete. All tests and inspections will be conducted so as not to interfere unnecessarily with manufacture and delivery of the concrete.

7. HANDLING AND MEASUREMENT OF MATERIALS

Materials shall be stockpiled and batched by methods that will prevent segregation or contamination of aggregates and insure accurate proportioning of the ingredients of the mix.

Except as otherwise provided in Section 8, cement and aggregates shall be measured as follows:

Cement shall be measured by weight or in bags of 94 pounds each. When cement is measured in bags, no fraction of a bag shall be used unless weighed.

Aggregates shall be measured by weight. Mix proportions shall be based on saturated, surface-dry weights. The batch weight of each aggregate shall be the required saturated, surface-dry weight plus the weight of surface moisture it contains.

Water shall be measured, by volume or by weight, to an accuracy within one percent of the total quantity of water required for the batch.

Admixtures shall be measured within a limit of accuracy of three percent.

8. MIXERS AND MIXING

Concrete shall be uniform and thoroughly mixed when delivered to the work site. Variations in slump of more than one (1) inch within a batch will be considered evidence of inadequate mixing and shall be corrected by increasing mixing time or other acceptable alternative.

For stationary mixers, the mixing time after all cement and aggregates are in the mixer drum shall be not less than 1-1/2 minutes. When concrete is mixed in a truck mixer, the number of revolutions of the drum or blades at mixing speed shall be not less than 70 nor more than 100.

Unless otherwise specified, volumetric batching and continuous mixing at the construction site will be permitted. The batching and mixing equipment shall conform to the requirements of ASTM Specification C 685 and shall be demonstrated prior to placement of concrete, by tests with the job mix, to produce concrete meeting the specified proportioning and uniformity requirements. Concrete made by this method shall be produced, inspected, and certified in conformance with Sections 6, 7, 8, 13, and 14 of ASTM Specification C 685.

No mixing water in excess of the amount called for by the job mix shall be added to the concrete during mixing or hauling or after arrival at the delivery point.

9. FORMS

Forms shall be of wood, plywood, steel or other approved material and shall be mortar tight. The forms and associated falsework shall be substantial and unyielding and shall be constructed so that the finished concrete will conform to the specified dimensions and contours. Form surfaces shall be smooth and free from holes, dents, sags or other irregularities. Forms shall be coated with a non-staining form release agent before being set into place.

Metal ties or anchorages within the forms shall be equipped with cones, she-bolts or other devices that permit their removal to a depth of at least one inch without injury

to the concrete. Ties designed to break off below the surface of the concrete shall not be used without cones.

All edges that will be exposed to view when the structure is completed shall be chamfered, unless finished with molding tools as specified in Section 18.

10. PREPARATION OF FORMS AND SUBGRADE

Prior to placement of concrete, the forms and subgrade shall be free of chips, sawdust, debris, water, ice, snow, extraneous oil, mortar, or other harmful substances or coatings and the temperature of all surfaces to be in contact with the new concrete shall be not be less than 40° F. Any oil on the reinforcing steel or other surfaces required to be bonded to the concrete shall be removed. Rock surfaces shall be cleaned by air-water cutting, wet sandblasting or wire brush scrubbing, as necessary, and shall be wetted immediately prior to placement of concrete. Earth surfaces shall be firm and damp. Placement of concrete on mud, dried earth or uncompacted fill or frozen subgrade will not be permitted.

Items to be embedded in the concrete shall be positioned accurately and anchored firmly.

Weepholes in walls or slabs shall be formed with nonferrous materials.

11. CONVEYING

Concrete shall be delivered to the site and discharged into the forms within 1-1/2 hours after the introduction of the cement to the aggregates. In hot weather or under conditions contributing to quick stiffening of the concrete, the time between the introduction of the cement to the aggregates and discharge shall not exceed 45 minutes.

The Engineer may allow a longer time, provided the setting time of the concrete is increased a corresponding amount by the addition of an approved set-retarding admixture. In any case, concrete shall be conveyed from the mixer to the forms as rapidly as practicable by methods that will prevent segregation of the aggregates and no loss of mortar occurs.

12. PLACING

Concrete shall not be placed until the subgrade, forms, steel reinforcement, and embedded items have been inspected and approved. No concrete shall be placed except in the presence of the Engineer. The Contractor shall give reasonable notice to the Engineer each time he intends to place concrete. Such notice shall provide sufficient time for the Engineer to inspect the subgrade, forms, steel reinforcement and other preparations for compliance with the specifications. "Other preparations" include but are not limited to the concrete mixing plant, delivery equipment system, placing, finishing, and curing equipment and system, schedule of work, workforce,

heating or cooling facilities if applicable. Deficiencies are to be corrected before concrete is delivered for placing.

The concrete shall be deposited as closely as possible to its final position in the forms and shall be worked into the corners and angles of the forms and around all reinforcement and embedded items in a manner to prevent segregation of aggregates or excessive laitance. Formed concrete shall be placed in horizontal layers not more than 20 inches thick. Concrete shall not be dropped more than five feet vertically unless suitable equipment is used to prevent segregation. When high range water reducing agents are used, the concrete shall not be allowed to drop more than 10 feet. Hoppers and chutes, pipes or "elephant trunks" shall be used as necessary to prevent segregation and the splashing of mortar on the forms and reinforcing steel above the layer being placed.

Immediately after the concrete is placed in the forms, it shall be consolidated by spading, hand tamping or vibration as necessary to insure smooth surfaces and dense concrete. Each layer shall be consolidated to insure monolithic bond with the preceding layer. If the surface of a layer of concrete in-place sets to the degree that it will not flow and merge with the succeeding layer when spaded or vibrated, the Contractor shall discontinue placing concrete and shall make a construction joint according to the procedure specified in Section 13.

If placing is discontinued when an incomplete horizontal layer is in place, the unfinished end of the layer shall be formed by a vertical bulkhead.

13. CONSTRUCTION JOINTS

Construction joints shall be made at the locations shown on the drawings. If construction joints are needed which are not shown on the drawings, they shall be placed in locations approved by the Engineer.

Where a feather edge would be produced at a construction joint, as in the top surface of a sloping wall, an insert form shall be used so that the resulting edge thickness on either side of the joint is not less than 6 inches.

In walls and columns, as each lift is completed, the top surfaces shall be immediately and carefully protected from any condition that might adversely affect the hardening of the concrete.

Steel tying and form construction adjacent to concrete in-place shall not be started until the concrete has cured at least 12 hours. Before new concrete is deposited on or against concrete that has hardened, the forms shall be re-tightened. New concrete shall not be placed until the hardened concrete has cured at least 12 hours.

Surfaces of construction joints shall be cleaned of all unsatisfactory concrete, laitance, coatings or debris by washing and scrubbing with a wire brush or wire broom or by other means approved by the Engineer. The surfaces shall be kept moist for at least one hour prior to placement of the new concrete.

14. EXPANSION AND CONTRACTION JOINTS

Expansion and contraction joints shall be made only at locations shown on the drawings.

Exposed concrete edges at expansion and contraction joints shall be carefully tooled or chamfered, and the joints shall be free of mortar and concrete. Joint filler shall be left exposed for its full length with clean and true edges.

Preformed expansion joint filler shall be held firmly in the correct position as the concrete is placed.

When open joints are specified, they shall be constructed by the insertion and subsequent removal of a wooden strip, metal plate or other suitable template in such a manner that the corners of the concrete will not be chipped or broken. The edges of open joints shall be finished with an edging tool prior to removal of the joint strips.

15. WATERSTOPS

Waterstops shall be held firmly in the correct position as the concrete is placed. Joints in metal waterstops shall be soldered, brazed or welded. Joints in rubber or plastic waterstops shall be cemented, welded or vulcanized as recommended by the manufacturer.

16. REMOVAL OF FORMS

Forms shall not be removed without the approval of the Engineer. Forms shall be removed in such a way as to prevent damage to the concrete. Supports shall be removed in a manner that will permit the concrete to take the stresses due to its own weight uniformly and gradually.

17. FINISHING FORMED SURFACES

Immediately after the removal of the forms:

- a. All fins and irregular projections shall be removed from exposed surfaces.
- b. The holes produced on all surfaces by the removal of form ties, cone-bolts, and she-bolts shall be cleaned, wetted and filled with a drypack mortar consisting of one part portland cement, three parts sand that will pass a No. 16 sieve, and just sufficient water to produce a consistency such that the filling is at the point of becoming rubbery when the material is solidly packed.

18. FINISHING UNFORMED SURFACES

All exposed surfaces of the concrete shall be accurately screeded to grade and then float finished, unless specified otherwise.

Excessive floating or troweling of surfaces while the concrete is soft will not be permitted.

The addition of dry cement or water to the surface of the screeded concrete to expedite finishing will not be allowed.

Joints and edges on unformed surfaces that will be exposed to view shall be chamfered or finished with molding tools.

19. CURING

Concrete shall be prevented from drying for a curing period of at least 7 days after it is placed. Exposed surfaces shall be kept continuously moist for the entire period, or until curing compound is applied as specified below. Moisture shall be maintained by sprinkling, flooding or fog spraying or by covering with continuously moistened canvas, cloth mats, straw, sand or other approved material. Wood forms left in-place during the curing period shall be kept continuously wet. Formed surfaces shall be thoroughly wetted immediately after forms are removed and shall be kept wet until patching and repairs are completed. Water or covering shall be applied in such a way that the concrete surface is not eroded or otherwise damaged.

Concrete, except at construction joints, may be coated with the approved curing compound in lieu of continued application of moisture, except as otherwise specified in Section 24. The compound shall be sprayed on the moist concrete surfaces as soon as free water has disappeared, but shall not be applied to any surface until patching, repairs and finishing of that surface are completed. The compound shall be applied at a uniform rate of not less than one gallon per 175 square feet of surface and shall form a continuous adherent membrane over the entire surface. Curing compound shall be thoroughly mixed before applying and continuously agitated during application. Curing compound shall not be applied to surfaces requiring bond to subsequently placed concrete, such as construction joints, shear plates, reinforcing steel and other embedded items. If the membrane is damaged during the curing period, the damaged area shall be re-sprayed at the rate of application specified above. Surfaces covered by the membrane shall not be trafficked unless protected from wear.

20. REMOVAL AND REPLACEMENT OR REPAIR

When concrete is honeycombed, damaged or otherwise defective, the Contractor shall remove and replace the structure or structural member containing the defective concrete or, where feasible, correct or repair the defective parts. The Engineer will determine the required extent of removal, replacement or repair. Prior to starting repair work the Contractor shall obtain the Engineer's approval of his plan for effecting the repair. The Contractor shall perform all repair work in the presence of the Engineer.

21. CONCRETING IN COLD WEATHER

Concrete shall not be mixed nor placed when the daily minimum atmospheric temperature is less than 40° F unless facilities are provided to prevent the concrete from freezing. The use of accelerators or antifreeze compounds will not be allowed.

22. CONCRETING IN HOT WEATHER

The Contractor shall apply effective means to maintain the temperature of the concrete below 90° F during mixing, conveying and placing.

23. MEASUREMENT AND PAYMENT

For items of work for which specific unit prices are established in the contract, concrete will be measured to the neat lines shown on the drawings and the volume of concrete will be computed to the nearest 0.1 cubic yard. Measurement of concrete placed against the sides of an excavation without the use of intervening forms will be made only to the neat lines or pay limits shown on the drawings. No deduction in volume will be made for chamfers, rounded or beveled edges or for any void or embedded item that is less than five (5) cubic feet in volume.

Payment for each item of structure concrete will be made at the contract unit price or the contract lump sum, whichever is applicable, for that item. Such payment will constitute full compensation for all labor, materials, equipment, transportation, tools, forms, falsework, bracing and all other items necessary and incidental to the completion of the work, except items listed for payment elsewhere in the contract.

Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 24 of this specification.

SHOTCRETE

1. APPLICABILITY

Construction Specification 33 is applicable to the placement of dry mix and wet mix shotcrete.

2. MATERIAL SPECIFICATIONS

The following specifications are complementary to Construction Specification 33:

- a. [Portland Cement Specification 531](#)
- b. [Aggregates Specification 522](#)
- c. [Curing Compounds Specification 534](#)

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Complete engineering drawings and structural detail drawings as specified in Section 6, National Engineering Handbook, including as a minimum:
 - (1) Plans and cross sections showing the surface dimensions and thickness of all shotcrete slabs, walls, or layers and neat pay lines.
 - (2) Reinforcement details including bar placement diagrams.
 - (3) Finish lines and grades.
 - (4) Joint and edge details.
- b. The condition or orientation of subgrade materials or surfaces. Identify wet areas that will require special treatment. Detail the special treatment that will be required (special shotcrete mixtures that may include silica fume and/or accelerators for flash sets, drainage blankets, special subsurface treatment, etc.).
- c. Notes as necessary to indicate special placement or finishing requirements.
- d. Type of cement.
- e. Special admixtures. i.e., silica fume, fibers, high range water reducers, air entraining, and accelerators. Calcium chloride shall not be used in shotcrete containing steel embedments.
- f. Required compressive strength.
- g. Nozzleman qualifications as stated in Section 6 are considered appropriate for most complex jobs with significant amount of concrete. Qualification requirements may be reduced for small, simple jobs as determined by the designer.

- h. Volumetric batching is permitted in Section 7 for projects with difficult access, small volumes of shotcrete, or low placement rates. Volume batching where permitted shall be specified in Section 19 by aggregate and cement batching by the bag or pre-blended dry cement and aggregate.

4. DISCUSSION OF METHODS

a. Section 18, Measurement and Payment

- (1) Method 1 is intended for use where shotcrete in place is to be reasonably uniform in shape and thickness so that measurement of the surface area will be feasible and will be representative of the amount of shotcrete placed.
- (2) Method 2 is intended for use where measurement of shotcrete in place will not be feasible or when payment by materials in place will not be feasible or when payment by materials used rather than shotcrete in place is desirable for other reasons.

When specifications are prepared using electronic procedures and all but one measurement and payment method are deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

33. SHOTCRETE

1. SCOPE

The work shall consist of furnishing, mixing, applying and curing shotcrete. Except as otherwise specified, either a dry mix or wet mix process may be used.

2. MATERIALS

[Portland cement](#) shall conform to the requirements of Material Specification [531](#) for the specified type.

[Aggregates](#) shall conform to the requirements of Material Specification [522](#) unless otherwise specified. Gradation shall be one of the three options specified by ACI 506R, Table 2.1 unless otherwise specified.

[Admixtures](#), if specified, shall meet the requirements indicated. Non-chloride chemical admixtures shall conform to ASTM C 494. Air-entraining admixtures shall conform to ASTM C 260. Fly ash or pozzolanic materials shall conform to ASTM C 618. Calcium chloride shall conform to ASTM D 98 and shall be in flake or pellet form.

Water used in mixing or curing shotcrete shall be clean and free from injurious amounts of oil, salt, acid, alkali, organic matter or other deleterious substances.

[Curing compound](#) shall conform to the requirement of Material Specification [534](#).

3. STRENGTH AND QUALITY

The compressive strength of shotcrete at the age of 28 days shall be not less than specified in Section 19 of this specification.

Shotcrete shall be uniform and dense, free from "drummy" areas that indicate laminations, voids, sand pockets, or disbanded material.

4. CONSISTENCY

The proportion of water added to the mixture shall be accurately controlled to produce thorough and uniform hydration of the shotcrete. The consistency of the shotcrete shall be such that the surface of the shotcrete in place shall have a rich, glossy appearance and that the shotcrete shall adhere to the supporting surface without flowing, slumping or sloughing. For application to vertical or overhanging surfaces the mix proportions shall be adjusted so that the placed shotcrete will adhere to a minimum thickness of 3/4-inch without sagging or sloughing. For adjustment of consistency the addition of fly ash or pozzolanic material to the mixture in amounts not greater than 20-percent (by weight) of cement in the mixture will be permitted.

5. INSPECTION AND TESTING

Procedures for preparing shotcrete test panels and the testing specimens sawed or cored from panels will be performed in accordance with ASTM Method C 1140. The compression test specimens will be cores taken from the test panels or from the structure.

Similar panels not less than 18 inches square and not less than six (6) inches thick shall be made periodically as directed by the Engineer during the progress of the work.

Cores, taken from the test panels, shall receive standard curing in lime-saturated water at $73.4^{\circ} \pm 3.0^{\circ}$ F within 24 hours after removal. Cores shall continue to receive the prescribed initial cure treatment until standard curing is commenced.

For each strength test, three (3) cores will be tested in compression. The test result will be the average of the strengths of the three (3) specimens, except that if one specimen shows manifest evidence of improper sampling, coring, or testing, it will be discarded and the strengths of the remaining two (2) specimens will be averaged. If more than one (1) specimen representing a test shows such defects, the entire test will be discarded.

The Contractor shall furnish the forms and make the required test panels and shall provide such facilities, materials and assistance as may be necessary for curing, handling, and protecting the panels. Test panels shall be cast only when the Engineer is present.

6. NOZZLE OPERATOR QUALIFICATIONS

The nozzle operator shall be able to document a minimum of 3000 hours of experience as a nozzle operator and shall have completed at least one (1) similar application as a nozzle operator, unless otherwise specified.

The nozzle operator and application crew members shall be required to meet pre-construction testing requirements administered by the Engineer on a test panel or an area as follows:

The Engineer will carefully observe shooting of the test panel or area and note if the nozzle operator examinee:

- a. Cleans the shooting surface with air and water prior to shooting.
- b. Applies a bonding coat on the shooting surface ahead of the heavier shotcrete applications.
- c. Directs shotcrete application around reinforcement in a manner which prevents buildup on the face of the reinforcement and allows the shotcrete to flow and compact tightly around the back of the reinforcement.

- d. If applicable, directs the finisher or nozzle helper to cutout any sags, sand or rebound pockets.
- e. If applicable, and where necessary, directs the finisher or nozzle helper to broom the shotcrete surface prior to application of additional layers.

7. MEASURING MATERIALS

The proportions of the shotcrete mix shall be controlled on the basis of the weight of each component material, unless otherwise specified in Section 19 of this specification, except that water may be measured by volume. Materials shall have the following batch tolerances of their mix proportion weights: Cement, plus or minus two (2) percent; Aggregate, plus or minus four

(4) percent; Admixtures, plus or minus six (6) percent. Weighing equipment used shall be accurate to within 0.4 percent of scale capacity.

8. EQUIPMENT

The Contractor shall furnish all equipment necessary for batching, mixing and placing the shotcrete. The equipment shall meet the following requirements.

The placing equipment for dry mix shotcrete shall be designed and equipped to receive the dry mix, introduce the mix into a stream of compressed oil free dry air, convey the mix pneumatically through a delivery hose to a nozzle at the point of discharge, inject water under pressure into the suspended stream of dry sand and cement within the nozzle, and spray the resulting shotcrete mix onto the surface of the work at a uniform rate and at a controlled velocity. The placing equipment shall be equipped with accurate gauges to indicate the air pressure and water pressure and with devices capable of accurately controlling the air pressure at any level between 50-psi and 80-psi, the water pressure at any level between 50-psi and 100-psi, and the rate of application of water at the nozzle.

The placing equipment for wet mix shotcrete shall be designed and equipped to receive the shotcrete from the mixer, convey it through a delivery hose to a nozzle at the point of discharge, accelerate it in the nozzle by means of compressed oil free dry air, and spray it onto the surface of the work. It shall be capable of delivering shotcrete to the nozzle uniformly and continuously and discharging it from the nozzle at a uniform rate and at a controlled velocity sufficient for all parts of the work.

Batch and continuous mixing equipment shall include: a power-driven mixer capable of thoroughly mixing the materials at a rate adequate to insure uniform feeding of the mixture to the placing equipment; and a feeding apparatus capable of supplying the mixture to the placing equipment at an adequate and uniform rate.

9. MIXING

Dry Mix Shotcrete The cement and admixtures and other additives (except accelerator) shall be mixed into a predampened homogeneous mass that thoroughly coats the aggregate before being fed through a vibratory screen into the placing equipment. Proper pre-dampening shall be indicated by the "ball-in-hand" test as follows: When a small amount of mix is tightly squeezed the resulting ball will hold together or crack slightly but essentially remain whole. The mix has too little pre-dampening moisture if the ball crumbles into discrete particles when the hand is opened and/or color is light gray. If moisture comes off on the hand, too much pre-dampening moisture is in the mix. The properly pre-dampened dry mix shall be used within 45 minutes after mixing (15 minutes in hot weather conditions with temperatures over 85° F) and any material that becomes dried out or caked after mixing shall be wasted. Rebound material shall not be remixed or reused.

Wet Mix Shotcrete Air-entrainment and chemical admixtures may only be used in wet mix concrete. The cement, sand, admixtures (except accelerator) and water shall be thoroughly mixed in the mixer drum sufficiently to produce shotcrete of the required consistency that is uniform within each batch and uniform from batch to batch when discharged into the placing equipment.

Accelerators, if specified, shall be mixed at the nozzle. Ready-mix concrete shall conform to the requirements of ASTM C 94 unless otherwise specified.

The entire contents of the mixer shall be discharged from the drum before materials for a succeeding batch are placed therein. A mix that becomes difficult to pump shall be discarded; otherwise, a batch shall be gunned within 1 1/2 hours of batching in normal weather and within 45 minutes during hot weather conditions (temperatures over 85° F). Rebound material shall not be remixed or reused.

10. FORMS

Forms shall be structurally adequate and of such design that rebound or accumulated loose sand can freely escape or be readily removed. Shooting strips shall be used at corners, edges, and on surfaces where necessary to obtain true lines and proper thickness. Where practicable, ground wires shall be installed as guides to accurately establish the specified contour of the finished surface of shotcrete. Ground wires shall be set and used as guides for templates in forming curved and molded surfaces. When shotcrete is to be placed on horizontal or sloping surfaces, headers and ground wires shall be provided to the extent necessary to insure control of slab thickness. Ground wires shall be tightened and kept taut, secure, and true to line and plane during placement of shotcrete and shall be removed when placement is completed.

Header boards will be required where the drawings indicate a square edge and at required joints. Form surfaces shall be thoroughly cleaned and a form release agent applied before shotcrete is placed.

11. PREPARATION OF SURFACES TO RECEIVE SHOTCRETE

All surfaces to receive or support shotcrete shall be carefully prepared and conditioned. All such prepared surfaces shall be inspected and approved by the Engineer prior to the application of shotcrete.

Earth surfaces to which shotcrete is to be applied shall be firmly compacted and neatly trimmed to line and grade.

Asphaltic concrete surfaces shall be thoroughly cleaned of any growths, earth, or any other material that would affect bond, or be detrimental to the shotcrete.

Concrete, mortar, or rock surfaces shall be thoroughly cleaned by water blasting or sand blasting to remove all dirt, laitance, weak or unbonded mortar, loose material, grease or other deleterious substances.

Surfaces on which the shotcrete is to be placed shall be sufficiently rough to insure the adherence of the shotcrete. Offsets which would cause an abrupt and substantial change in thickness of the shotcrete shall be removed or tapered.

All surfaces shall be maintained in a moistened condition for three (3) hours before application of shotcrete. Shotcrete shall not be applied to mud, dried earth, uncompacted fill, rebound material, or surfaces on which free water exists unless otherwise specified in Section 19. All ice, snow and frost shall be removed and the temperature of all surfaces, to be in contact with the new shotcrete shall be no colder than 40° F.

12. PLACING

The Contractor shall have all equipment and materials required for curing available at the site and ready for use before placement of shotcrete begins. No shotcrete shall be placed except in the presence of the Engineer or authorized representative. The Contractor shall give reasonable notice to the Engineer each time shotcrete placement is scheduled. Such notice shall be far enough in advance to give the Engineer adequate time to inspect the surfaces to which the shotcrete is to be applied, the forms, steel reinforcement, and other preparations for compliance with the specifications prior to the start of placement operations.

During placement of shotcrete the air pressure shall be adjusted as required to control rebound and density of shotcrete. For a given application, once the optimum operating pressures have been established they shall be maintained constant throughout the application. For dry mix shotcrete, the air pressure at the material outlet or air-inlet on the gun shall be not less than 40 psi plus 5 psi for each 50 feet of length of the discharge hose greater than 100 feet and 5 psi for each 25 feet the nozzle is above the gun (shotcrete delivery equipment). The water pressure at the nozzle shall be not less than 15 psi greater than the air pressure at the material outlet or air-inlet on the gun.

For most applications the placing nozzle shall be held between two (2) and six (6) feet from and approximately normal to the surface of the work. At longer distances it may be necessary to increase the nozzle velocity so that the impact velocity will suit the requirements of the application. Corners shall be filled first.

Shotcrete shall be applied in a single thickness or to a layer thickness no greater than that which will cause sagging, sloughing, or dropout. Sags and sloughs shall be cut out and regunned. Replacement shall be accomplished before the previously placed shotcrete has completely set. When shotcrete is placed on a vertical surface, application shall be started at the bottom and be completed at the top.

In any case when the placing of shotcrete is interrupted for more than one (1) hour, the edge of the layer shall be sloped off at an angle of approximately 45 degrees to the surface being shot, and the sloped portion shall be covered with a double layer of six (6) ounce burlap and kept continuously moist until the application of shotcrete is resumed. Before applying new material, the sloped portion shall be thoroughly cleaned and wetted by means of an air and water blast or an equally effective method approved by the Engineer.

Material that rebounds and accumulates on forms, subgrade surfaces or reinforcing steel ahead of the shotcrete being placed shall be removed and discarded.

13. FINISHING

Rebound material shall be carefully swept off the finished shotcrete surface and discarded before it becomes too hard for removal. After the shotcrete has been placed to the depth required, the surface shall be checked with a straightedge or template and any low spots shall be brought up to grade by placing additional shotcrete. The finished surface of the shotcrete shall be left as a natural gun finish unless screeding and or further finishing are specified in Section 19 of this specification.

When specified screeding shall be accomplished as follows: Place shotcrete a fraction beyond the guide strips, ground wires or forms. Allow the surface of the shotcrete to stiffen to the point it will not pull or crack under screeding or troweling. Trim, slice, or scrape excess material to true line and grade and remove the placing guides.

A natural rod finish shall consist of the removal, by floating, of the impressions left after the guide strips or ground wires have been removed.

A natural broom finish shall be that finish resulting from brooming the natural rod finish.

A float finish shall be that finish resulting from floating the natural rod finish with a wood or rubber float.

14. CURING

Shotcrete shall be prevented from drying for a curing period of at least seven (7) days after it is placed. Exposed surfaces shall be kept continuously moist for the entire period or until curing compound is applied as specified below. Moisture shall be maintained by sprinkling, flooding or fog spraying, or by covering with continuously moistened canvas, cloth mats, straw, sand or other approved material. Wood forms left in place during the curing period shall be kept wet. Formed surfaces shall be thoroughly wetted immediately after forms are removed and shall be kept wet until patching and repairs are completed. Water, or covering, shall be applied in such a way that the shotcrete surface is not eroded or otherwise damaged.

Water for curing shall be clean and free from any substances that will cause discoloration of the shotcrete where finished surfaces will be exposed to view.

Except as otherwise specified in Section 17 d. of this specification, and except for surfaces to which additional shotcrete is to be applied, shotcrete may be coated with curing compound as an alternative to the continued application of moisture.

The compound shall be sprayed on the moist shotcrete surfaces as soon as rebound has been removed and any required repairs are completed, or as soon as water curing is discontinued.

The curing compound shall be thoroughly mixed immediately before applied and continuously agitated during application. It shall be applied at a uniform rate of not less than one (1) gallon per 100 square feet of surface for natural gun finishes. Curing compound shall be applied in two (2) applications, one (1) in each direction. If a natural rod, broom, or float finish is specified, the curing compound application rate shall be at least one (1) gallon per 150 square feet. Curing compound shall not check, crack or peel, and shall be free from pinholes or other imperfections.

Curing compound shall not be applied to subgrade surfaces or other surfaces requiring bond with subsequently placed shotcrete, such as construction joints, reinforcing steel and other embedded items.

Surfaces subjected to heavy rainfall or running water within three (3) hours after the compound has been applied, or surfaces damaged by subsequent construction operations during the curing period shall be resprayed in the same manner as for the original applications.

Surfaces covered by the membrane shall not be trafficked unless protected from damage and/or wear.

15. REPLACEMENT OR REPAIR

When shotcrete lacks uniformity, exhibits segregation, honeycombing, or laminations, or contains dry patches, slugs, voids or sand pockets the Contractor

shall remove and replace the defective shotcrete. The Engineer's concurrence in the extent of removal and replacement is required.

Prior to starting significant removal and replacement work the Contractor shall obtain the Engineer's approval of their plan for making the repair. Such approval shall not be considered a waiver of the Contracting Officer's or owner's right to require complete removal of defective work if the completed repair does not produce shotcrete of the required quality and appearance.

Repair work shall be performed only when the Engineer is present.

Repair shall be made with shotcrete conforming to this specification. When removal of defective shotcrete is required, reinforcement damaged or destroyed shall be replaced prior to replacement of the shotcrete. At the edges of removed sections the sound shotcrete shall be carefully trimmed to the extent required to expose sufficient reinforcement for effecting competent splices. The sound shotcrete at the edges of removed sections shall be trimmed to a slope of approximately 45 degrees with the surface of the work and shall be thoroughly moistened prior to placement of the new shotcrete.

Any portions of the work having thickness less than those specified may be repaired by the placement of additional layers of shotcrete, provided that such repair is expressly approved by the Engineer.

Surfaces of the work to which additional shotcrete is to be applied shall be prepared as required by Section 11 of this specification.

Curing as specified in Section 14 of this specification shall be applied to repaired areas immediately after the repairs are completed.

16. PLACING IN COLD WEATHER

When the atmospheric temperature may be expected to drop below 40° F at the time shotcrete is placed, or at any time during the curing period, the following provisions shall also apply:

- a. Shotcrete placement shall be permitted when the air temperature is at least 40° F and rising. Placement shall be discontinued if the temperature falls to 40° F and is expected to continue to fall.
- b. The temperature of the shotcrete at time of placing shall not be less than 50° F nor more than 90° F. The temperature of neither aggregates nor mixing water shall be more than 100° F just prior to mixing with the cement.
- c. When the daily minimum temperature is less than 40° F, shotcrete shall be insulated or housed and heated after placement. The temperature of the shotcrete and air adjacent to the shotcrete shall be maintained at not less than 50° F nor more than 90° F for the duration of the curing period.

- d. Methods of insulating, housing and heating the structure shall be in accordance with "Standard Specification for Cold Weather Concreting," ACI Standard 306.1.
- e. The use of accelerators or antifreeze compounds will not be allowed unless otherwise specified.
- f. When dry heat is used to protect shotcrete, means of maintaining an ambient humidity of at least 40 percent shall be provided unless the shotcrete has been coated with curing compound as specified in Section 14 of this specification or is covered tightly with an approved impervious material.

17. PLACING IN HOT WEATHER

When climatic factors such as high air temperature, reduced relative humidity and increased wind velocities are present, or conditions are such that the temperature of placed shotcrete exceeds 90° F at, or during the first 24 hours after placement, the following provisions shall also apply:

- a. The Contractor shall maintain the temperature of the shotcrete below 90° F during mixing, conveying, and placing using the methods given in items b, c, and d below.
- b. Exposed shotcrete surfaces which tend to dry or set too rapidly shall be continuously moistened by means of fog sprays or otherwise protected from drying immediately after placement.
- c. Shotcrete surfaces exposed to the air shall be covered as soon as the shotcrete has hardened sufficiently and shall be kept continuously wet for at least the first 24 hours of the curing period, and for the entire curing period unless curing compound is applied as specified in Subsection d., below.
- d. If moist curing is discontinued before the end of the curing period, white pigmented curing compound shall be applied immediately, following the procedures specified in Section 14 of this specification.

18. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established in the contract, the dimensions of the exposed surface of the shotcrete will be measured to the neat lines shown on the drawings and the surface area will be computed to the nearest square foot. Payment will be made at the contract unit price for shotcrete. Such payment will constitute full compensation for completion of the work, including making and handling test panels but not including reinforcing steel or other items listed for payment elsewhere in the contract.

Measurement and payment for furnishing and placing reinforcing steel will be made as specified in Construction Specification 34.

Method 2 For items of work for which specific unit prices are established in the contract, cement and aggregates used in shotcrete and in authorized test panels will be measured by the batch weights of the materials charged into the mixer. No deduction will be made for normal rebound; however, payment will not be made for material wasted because the in-place shotcrete does not conform to the specifications. Payment will be made at the contract unit prices for cement and aggregates for shotcrete. Such payment will constitute full compensation for completion of the work, including making and handling test panels but not including reinforcing steel or other items listed for payment elsewhere in the contract.

Measurement and payment for furnishing and placing reinforcing steel will be made as specified in Construction Specification 34.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 19 of this specification.

STEEL REINFORCEMENT

1. APPLICABILITY

Construction Specification 34 is applicable to the placement of steel bar reinforcement and steel welded wire fabric reinforcement for reinforced concrete or pneumatically applied mortar.

2. MATERIAL SPECIFICATIONS

Steel Reinforcement. Material Specification 539 is complementary to Construction Specification 34.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Complete placing drawings prepared by the designer or instructions for the Contractor to prepare placement drawings with steel schedules from the engineering drawings.
- b. Steel schedule and bar list with bending diagram if needed to facilitate the placement drawings. These are usually needed for all except simple structures.
- c. Type and grade of steel if it is necessary to restrict the Contractor's choice from the list in Material Specification 539.
- d. Bar splice requirements are normally covered by the ACI Codes and should be referenced. Unique limitations or exceptions need be included to provide clarity.
- e. Standard Methods would include the following to be used to specify bar splice lengths. There is an option to use one of two methods in specifying lap lengths at bar splices. The required information will vary depending upon the method used.
 - (1) Method 1 show splice locations along with lengths of bars in a schedule that is adequate to meet the design requirements and criteria.
 - (2) Method 2 include the following:
 - (a) Locations where splices are permitted or not.
 - (b) Type of splices at locations permitted contact, non-contact or butt.
 - (c) Splice layout at locations permitted staggered or coincident and alternating or repeated in Section 10.
 - (d) Splice class for each respective location and mat.
 - (e) Concrete design compressive strength, $f'c$.
 - (f) Bar stress condition - tension or compression.

- (g) Designation of "top bars" and "others".
- (h) Steel reinforcement design yield strength.
- f. Method(s) of measurement and payment, if the standard specification includes more than one method.

4. DISCUSSION OF METHODS

a. Section 5, Splicing Bar Reinforcement.

- (1) Method 1 is intended for use when construction drawings for reinforced concrete structures show bar placement details and steel schedules listing bar dimensions and bar shape. Splice locations and bar laps have been determined during design and fully detailed on the drawings. This method will apply when National Standard detail drawings are used.
- (2) Method 2 is intended for use when construction drawings do not contain complete bar placement diagrams and bar schedules. This method should be considered when quality control and other responsibilities are placed on the Contractor. Complete bar placement - drawings and schedules should normally be included in all construction drawings. However, in such cases when engineering drawings are prepared by a project sponsor or an A-E firm and complete bar placement drawings and schedules are not provided, they may be prepared by the steel fabricator based on engineering drawings as shown in ACI 315.

b. Section 9, Measurement and Payment.

- (1) Method 1 is intended for use when all reinforcement is measured by weight.
- (2) Method 2 is intended for use when bar reinforcement is measured by weight and welded wire fabric reinforcement is measured by area.

When specifications are prepared using electronic procedures and all but one measurement and payment method are deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

34. STEEL REINFORCEMENT

1. SCOPE

The work shall consist of furnishing and placing steel reinforcement for reinforced concrete or pneumatically applied mortar.

2. MATERIALS

Steel reinforcement shall conform to the requirements of Material Specification 539. Before reinforcement is placed, the surfaces of the bars and fabric and any metal supports shall be cleaned to remove any loose, flaky rust, mill scale, oil, grease or other undesirable coatings or foreign substances. Epoxy-coated steel reinforcement shall be free of surface damage. After placement, the reinforcement shall be maintained in a clean and serviceable condition until it is completely embedded within the concrete.

3. BAR SCHEDULE, LISTS AND DIAGRAMS

Any supplemental bar schedules, bar lists or bar-bending diagrams required in Section 10 of this specification to accomplish the fabrication and placement of steel reinforcement shall be provided by the Contractor. Prior to placement of reinforcement, the Contractor shall furnish four copies of any such lists or diagrams to the Engineer for approval. Acceptance of the reinforcement will not be based on approval of these lists or diagrams, but will be based on inspection of the steel reinforcement after it has been placed, tied, supported and ready to receive concrete.

4. BENDING

Reinforcement shall be cut and bent in compliance with the requirements of the American Concrete Institute Standard 315. Bars shall not be bent or straightened in a manner that will injure or weaken the material. Bars with kinks, cracks or improper bends will be rejected.

5. SPLICING BAR REINFORCEMENT

Method 1 Splices of reinforcement shall be made only at locations shown on the drawings and provided by the steel schedule. Placement of bars at the lap splice locations shown, when not in contact, shall not be farther apart than one-fifth (1/5) the shown lap length and in any case no greater than six (6) inches.

Method 2 Splices of reinforcement shall be limited to those locations shown on the drawings. Splice lengths shall be determined prior to fabrication and meet the requirements of ACI Standard 318 "Building Code Requirements for Reinforced Concrete" based upon design information contained in Section 10 of this specification. Bar placement drawings and schedules shall be provided for approval prior to fabrication. The drawings shall show all splice locations, layouts, and lap dimensions.

6. SPLICING WELDED WIRE FABRIC

Unless otherwise specified, welded wire fabric shall be spliced in the following manner:

- a. Adjacent sections shall be spliced end to end (longitudinal lap) by overlapping a minimum of one full mesh plus two (2) inches plus the length of the two end overhangs. The splice length is measured from the end of the longitudinal wires in one piece of fabric to the end of the longitudinal wire in the lapped piece of fabric.
- b. Adjacent sections shall be spliced side to side (transverse lap) a minimum of one full mesh plus two (2) inches. The splice length shall be measured from the centerline of the first longitudinal wire in one piece of fabric to the centerline of the first longitudinal wire in the lapped piece of fabric.

7. PLACING

Reinforcement shall be accurately placed and secured in position in a manner that will prevent its displacement during the placement of concrete. Tack welding of bars will not be permitted. Metal chairs, metal hangers, metal spacers and concrete chairs may be used to support the reinforcement. Metal hangers, spacers and ties shall be placed in such a manner that they will not be exposed in the finished concrete surface. The legs of metal chairs or side form spacers that may be exposed on any face of slabs, walls, beams or other concrete surfaces shall have a protective coating or finish by means of hot dip galvanizing, epoxy coating, plastic coating, or be stainless steel. Metal chairs and spacers not fully covered by a protective coating or finish shall have a minimum cover of 3/4 inch of concrete over the unprotected metal portion except for those with plastic coatings may have a minimum cover of 1/2 inch of concrete over the unprotected metal portion. Pre-cast concrete chairs shall be manufactured of the same class of concrete as specified for the structure and shall have the tie wires securely anchored in the chair or a V-shaped groove at least 3/4 inch in depth molded into the upper surface to receive the steel bar at the point of support. Pre-cast concrete chairs shall be clean and moist at the time concrete is placed.

High density or structural plastic rebar accessories, designed to insure maximum concrete bond, may be substituted for metal or concrete accessories in spacer applications as approved by the Contracting Officer. Exposure of plastic rebar accessories at the finished concrete surface shall be kept to a minimum. Plastic rebar accessories, when used, shall be staggered along adjacent parallel bars and shall be placed at intervals no closer than twelve (12) inches. Plastic rebar accessories shall not be used in concrete section six (6) inches or less in thickness.

Reinforcement shall not be placed until the prepared site has been inspected and approved. After placement of the reinforcement, concrete shall not be placed until the reinforcement has been inspected and approved by the Engineer.

8. STORAGE

Steel reinforcement stored at the work site shall be placed on platforms, skids or other supports and in a manner that contact with the ground is avoided and be protected from mechanical damage and/or corrosion.

9. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established in the contract, the weight of steel reinforcement placed in the concrete in accordance with the drawings will be determined to the nearest pound by computation from the placing drawings. Measurement of hooks and bends will be based on the requirements of ACI Standard 315. Computation of weights of reinforcement will be based on the unit weights established in Tables 34-1 and 34-2 of this specification. Computation of weights for welded wire fabric not shown in Table 34-2 shall be based on ACI Standard 315. The area of welded wire fabric reinforcement placed in the concrete in accordance with the drawings will be determined to the nearest square foot by computation from the placing drawings with no allowance for required laps. The weight of steel reinforcing in extra splices or extra-length splices approved for the convenience of the Contractor or the weight of supports and ties will not be included in the measurement for payment.

Payment for furnishing and placing reinforcing steel will be made at the contract unit price. Such payment will constitute full compensation for all labor, materials, equipment and all other items necessary and incidental to the completion of the work including preparing and furnishing bar schedules, lists or diagrams; furnishing and attaching ties and supports; and furnishing, transporting, storing, cutting, bending, cleaning and securing all reinforcements.

Method 2 For items of work for which specific unit prices are established in the contract, the weight of bar reinforcement placed in the concrete in accordance with the drawings will be determined to the nearest pound by computation from the placing drawings. Measurement of hooks and bends will be based on the requirements of ACI Standard 315. Computation of weights of bar reinforcement will be based on the unit weights established in Table 34-1 of this specification. The weight of steel reinforcing in extra splices or extra length splices approved for the convenience of the Contractor or the weight of supports and ties will not be included in the measurement for payment.

The area of welded wire fabric reinforcement placed in the concrete in accordance with the drawings will be determined to the nearest square foot by computation from the placing drawings with no allowance for required laps.

Payment for furnishing and placing bar reinforcing steel will be made at the contract unit price for bar reinforcement. Payment for furnishing and placing welded wire fabric reinforcing steel will be made at the contract unit price for welded wire fabric reinforcement. Such payment will constitute full compensation for all labor,

materials, equipment and all other items necessary and incidental to the completion of the work including preparing and furnishing bar schedules, lists or diagrams; furnishing and attaching ties and supports; and furnishing, transporting, cutting, bending, cleaning, and securing all reinforcement.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract, but not listed in the bid schedule, will be included in the payment for the item of work to which it is made subsidiary. Such items to which they are made subsidiary are identified in Section 10 of this specification.

4 x 12 – 7 x 11	4 x 12 – W 2.5 x W 1.1*	31

NOTE: Style Designation is defined in ACI Standard 315 of the American Concrete Institute.

*Welded smooth wire fabric with wires smaller than Size W1.4 is manufactured from galvanized wire.

CONCRETE REPAIR

1. APPLICABILITY

Construction Specification 35 is applicable to the usual types of concrete repair entailed in NRCS operations. Supplementary specifications will be required for works of a special nature, such as:

- a. Placing concrete repair under water.
- b. Concrete repair exposed to sea or salt water.
- c. Concrete repair exposed to alkali soils or alkaline water.
- d. Special surface finishes.

2. MATERIAL SPECIFICATIONS

The following specifications are complementary to Construction Specification 35:

- a. [Aggregates. Specification 522](#)
- b. [Portland Cement. Specification 531](#)
- c. [Fly Ash. Specification 532](#)
- d. [Water-Reducing, Set-Retarding Admixtures. Specification 533](#)
- e. [Air-Entraining Admixtures. Specification 532](#)
- f. [Curing compounds. Specification 534](#)

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Complete engineering and structural detail drawings of the repair.
- b. Notation of the type and quality of concrete, including:
 - (1) Strength of concrete repair material if other than 4000 psi.
 - (2) Type of cement.
 - (3) Types of admixtures, if any.
 - (4) Nominal size of coarse aggregate; or specification for aggregate if Material Specification [522](#) does not apply.
 - (5) Authorization for a design mix that includes pozzolan as a partial substitute for cement.

- (6) Deviations from the air content, if any.
- (7) If replacement concrete is permitted, specify slump of the non-plasticized concrete mixture.
- c. Notation of which strength test procedure is to be used when ASTM C 684 is used.
- d. If volumetric batching and continuous mixing is not permitted, include statement to that effect.
- e. Deviations, if any, from specifications requiring:
 - (1) Placement of concrete repair in a single continuous pour.
 - (2) Consolidation of concrete repair material with vibrators.
- f. Finish requirements for unformed surfaces if other than float finish is designated.

4. DISCUSSION OF METHODS

a. Section 17, Measurement and Payment

- (1) Method 1 is intended for use when the actual approved volume of the repair will be calculated to determine payment.
- (2) Method 2 is intended for use when proprietary repair methods are used and the major components come in pre-measured and pre-packaged units. The size of a unit should be discussed in Section 18.
- (3) Method 3 is intended for use when the actual approved surface area of the repair will be calculated to determine payment.

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

35. CONCRETE REPAIR

1. SCOPE

The work shall consist of removal of unsuitable concrete; surface and face preparation; forming; and furnishing, placing, finishing, and curing concrete repair material as required to repair structures designated in Section 18 of this specification.

2. MATERIALS

Aggregates shall conform to the requirements of Material Specification 522 unless otherwise specified. The grading of coarse aggregates shall be as specified in Section 18, shown on the drawings, or as specified by the manufacturer of a proprietary repair material.

Portland cement shall conform to the requirements of Material Specification 531 for the specified type. Only one brand of any type of cement shall be used in any single repair as defined in Section 18.

Water used in mixing and curing of the concrete repair shall be clean and free from injurious amounts of oil, salt, acid, alkali, organic matter or other deleterious substances.

Fly Ash shall conform to the requirements of Material Specification 532.

Air-entraining admixtures shall conform to the requirements of Material Specification 533. If air-entraining cement is used, any additional air-entraining admixture shall be the same type as that in the cement.

Chemical admixtures for water-reducing, retarding, or water-reducing and retarding shall conform to the requirements of Material Specification 533.

Curing compound shall conform to the requirements of Material Specification 534.

Construction Specification 33, Shotcrete.

Proprietary concrete repair materials shall be subject to review and approval of the Engineer prior to use. The material shall meet all specified salient features for repair materials and not react detrimentally with the existing concrete or associated member of the structure being repaired.

Replacement concrete repair materials shall be a material that consists essentially of a binding medium of portland cement and water that will meet all the specified salient features for repair materials and not react detrimentally with the existing concrete or associated members of the structure being repaired. This may be, but is not limited to, a conventional concrete mix with or without admixtures, shotcrete, pre-placed aggregate concrete, or grout.

3. PREPARATION OF AREAS TO BE REPAIRED

All loose, cracked or otherwise unsuitable or defective concrete shall be removed from the existing structure as shown on the drawings or specified in Section 18. The final extent of removal shall be determined by the Engineer after inspection of prepared surfaces.

Feathered edges at the surface will not be permitted. The surface edge of the repaired area shall be cut with a saw, drilled, or chipped to leave a sharp edge with a minimum of a 3/4-inch depth face perpendicular to the face of the wall.

The top-side of the repair hole shall be shaped to a uniform fairly straight face which is sloped upward on a one (1) inch rise for each three (3) inches of depth of cut toward the face from which the repair material will be placed. The repair hole shall be conical in shape with the large end at the surface from which repair material will be placed.

The bottom and vertical or near vertical sides of the hole shall be cut sharply and approximately perpendicular to the face of the wall. All interior corners shall be rounded to a minimum radius of one (1) inch.

Where reinforcement is encountered, the concrete directly in contact with the sides of the reinforcement shall be removed to provide at least 1-inch clear distance between the reinforcement and the in-place concrete.

Prior to placement of concrete repair material, all oil and/or grease shall be steam or solvent cleaned from all reinforcement and surfaces to which the repair materials are required to bond. If solvent cleaning is used, solvents and solvent residues shall not impair the repair material or its bonding strengths.

After removal of all oil and grease, the reinforcement shall be cleaned to remove any loose, flaky rust, mill scale, and other coatings or foreign substances that would impair bonding of the repair material to the reinforcement. The prepared faces of the repair hole shall be cleaned by high pressure water jets or compressed air jetting with water to remove all loose particles and dust. The repair hole shall be free of chips, sawdust, debris, free water, ice, snow, or other harmful substances or coatings.

4. DISPOSAL

Unless otherwise specified, all concrete and other debris resulting from the repair works shall be removed from the site and disposed of at location(s) of the Contractor's selection. The Contractor is responsible for complying with all local, state, and federal regulations pertaining to the disposal of such waste.

5. SELECTION OF CONCRETE REPAIR MATERIAL

Only one brand of proprietary concrete repair material shall be used in any single repair operation unless compatibility between brands can be proven with actual test or performance data.

A conventional concrete mix to be used as a replacement concrete repair material shall be ready-mix concrete that will meet all the specified salient features for repair materials and conform to ASTM C 94. Option A from Section 5 of ASTM C 94 shall apply.

The Contractor will be responsible for the selection and correct application of the concrete repair material. At least 14-days prior to installation, the Contractor shall provide the Engineer for approval all technical data for the repair material. The technical data shall include the design mix and test results to verify satisfactory conformance to the salient feature requirements. If a proprietary material is used, the manufacturer's recommended preparation, use, and installation specifications shall also be submitted 14-days prior to installation. Concrete repair materials shall not be placed prior to approval.

Concrete repair material shall have the following salient features:

- a. Be a cementitious material that after hardening will remain stable in wet and moist environments and will not dissolve in water.
- b. A 28-day compressive strength of 4000 psi or greater when tested according to ASTM C 39, unless otherwise specified.
- c. Bond strength of the repair material shall be tested in accordance with ASTM C 882 procedures for Type V material and shall have the minimum strength of 1100 psi at 28-days unless otherwise specified.
- d. Shall be suitable for application at the minimum temperature of 55 degrees Fahrenheit.
- e. Shall not contain chlorides, added gypsum, added lime, or high alumina cements. Shall be non-combustible, both before and after cure.
- f. Color shall be concrete gray unless otherwise specified.
- g. Shall not produce a vapor barrier material and shall be thermally compatible with concrete.
- h. Shall have a freeze-thaw resistance equal to or greater than 4000 psi, air-entrained concrete designed for severe exposure conditions according to ACI Standard Practice 211.1, unless otherwise specified.

- i. Shall exhibit no shrinkage at 28-days and not greater than 0.4% expansion at 3, 14, or 28-days after placement when tested according to the procedures in Corps of Engineers Specification for Non-shrink Grout, CRD-C 621.

Additional site specific requirements for materials are defined in Section 18.

6. HANDLING AND MEASUREMENT OF MATERIAL

For all types of repair materials, the cementitious components shall be kept dry and protected from contamination until incorporated in the mix. Broken containers or bags of pre-measured and pre-mixed components will not be accepted.

Handling and measurement of conventional concrete mix repair material shall conform to ASTM C 94.

Handling and measurement of pre-packaged proprietary materials shall follow the manufacturer's recommendations and requirements. Handling and measurement of components which are not pre-packaged or pre-measured shall be in accordance with the requirements listed below and the manufacturer's requirements. A copy of the manufacturer's written requirements will be provided to the Engineer 14-days prior to installation.

Handling and measurement of proprietary components which are not pre-measured shall be handled and measured in the following manner:

Aggregates shall be stored or stockpiled in such a manner that separation of coarse and fine particles of each size will be avoided and that various sizes will not become intermixed before proportioning. Methods of handling and transporting aggregates shall be such as to avoid contamination, excessive breakage, segregation or degradation, or intermingling of various sizes.

Scales for weighing aggregates and repair material components shall be beam type, electronic or springless dial type. They shall be accurate within 0.4-percent under operating conditions. All exposed fulcrums, clevises and similar working parts of scales shall be kept clean and properly maintained.

The quantities by weight of repair material components and aggregates in each batch of material, as indicated by the scales, shall be within the following percentage of the required batch weights:

Aggregates	plus or minus two (2) percent
Other components	plus or minus one (1) percent

Measuring tanks for mixing water or liquid shall be of adequate capacity to furnish the maximum amount of mixing water or liquid required per approved batch. Measuring tanks shall provide the means for readily and accurately measuring the amount of water or liquid required. Accuracy of water measurement shall be plus or minus one (1) percent.

7. FORMS

Forming material shall be wood, plywood, steel or other approved material and shall be mortar tight. The forms and associated false-work shall be substantial and unyielding and shall be constructed so that the finished repair will conform to the specified dimensions and contours. Form surfaces shall be smooth and free from holes, dents, sags or other irregularities.

To prevent bonding of the repair materials to the forms, prior to setting the forms into place, the surface of the form shall be lined with plastic sheeting or coated with a non-staining form release agent compatible with the repair material being used. If the forms are lined with plastic, the plastic shall be stretched taut removing all wrinkles and folds and maintain a smooth condition during the placement and curing of the repair material.

Metal ties or anchorage within the forms shall be equipped with cones, she-Bolts or other devices that permit their removal to a minimum depth of one (1) inch without injury to the concrete or repair material. Ties designed to break-off below the surface of the concrete shall not be used without cones.

All visible edges and corners included in the repair location shall be shaped the same as adjacent or similar edges or corners of the structure being repaired.

Forms shall be constructed to facilitate consolidation and complete filling of the repair void, and when all surfaces are formed, to facilitate applying pressure to the repair material immediately after placement.

8. MIXING, CONVEYING AND PLACING

Proprietary repair material shall be mixed and conveyed to the forms according to manufacturer's written recommendations. Material that cannot be placed within the manufacturer's time requirements shall not be placed in the forms and shall be discarded off-site at locations selected by the Contractor.

Concrete repair material shall not be placed until the subgrade, forms and steel reinforcement have been inspected and approved by the Engineer.

The Contractor shall have all equipment and materials required for curing available at the site ready for use before placement of repair material begins.

No concrete repair material shall be placed except in the presence of the Engineer. The Contractor shall give reasonable notice to the Engineer each time concrete repair material is scheduled for placement. Such notice shall be adequate to allow the Engineer sufficient time to review and approve the subgrade, forms, steel reinforcement and other preparations for compliance with the specifications. Other preparations include, but are not limited to, the mixing and delivery equipment and system, placing and finishing equipment and system, schedule of work, work force,

and heating and cooling facilities as applicable. All deficiencies are to be corrected before concrete repair material is mixed for placement.

The concrete repair material shall be deposited as closely as possible to its final position in the forms and shall be worked into the corners and angles of the forms and around all reinforcement and embedded items in a manner to prevent segregation of aggregates or excessive laitance. The depositing of repair material shall be regulated so that the material can be consolidated with a minimum of lateral movement.

Unless otherwise approved, concrete repair material shall not be dropped from a height greater than recommended by the manufacturer or five (5) feet whichever is less.

Unless otherwise specified, all concrete repair material required for each repair location shall be placed in one continuous operation. Successive layers or batches shall be placed at a rate sufficient to prevent setting of material between successive layers.

At the time of placement of repair material, existing concrete surfaces shall be damp, without free water, unless otherwise specified or required by manufacturer of the proprietary repair material being used.

9. CONSOLIDATING

Concrete repair materials shall be consolidated to ensure positive contact of repair material with all repair surfaces and reinforcing steel, to remove entrapped air pockets and voids, and to maximize the density of the repair material.

Vibration shall not be applied directly to the reinforcing steel or other embedded items, the forms, or to concrete repair material that has hardened to the degree that it is no longer plastic.

The use of vibrators to transport concrete repair material in the forms or conveying equipment will not be allowed.

Proprietary repair material shall be consolidated in accordance with the manufacturer's recommendations.

Unless otherwise specified in Section 18, conventional concrete mix repair material shall be consolidated in the following manner:

Conventional concrete mix repair material shall be consolidated with internal type mechanical vibrators capable of transmitting vibration to the concrete at frequencies not less than 8000 impulses per minute. Vibration shall be supplemented by spading, rodding, or hand tamping, as necessary to insure smooth and dense concrete along form surfaces, in corners, and around embedded items.

The location, manner, and duration of the application of the vibrators shall be such as to secure maximum consolidation of the concrete repair material without causing segregation of the mortar and coarse aggregate, and without causing water or cement paste to flush to the surface. Vibration shall compact the concrete repair material and bring it into intimate contact with the forms and embedded items while removing voids and pockets of entrapped air.

The Contractor shall provide a sufficient number of vibrators to properly consolidate the concrete repair material immediately after it is placed. Vibration shall be applied to the freshly deposited concrete repair material by slowly inserting and removing the vibrator at points uniformly spaced and not farther apart than twice the radius of action; i.e., the distance that the concrete repair material is visibly effected by the vibration. The area visibly effected by the vibrator shall overlap the adjacent, just vibrated area. The vibrator shall extend vertically into the previously placed layer of fresh concrete repair material, at all points, to insure effective bond between layers. In thin slabs, the vibrator(s) should be sloped toward the horizontal to allow operations in a fully embedded position.

The internal vibration of thin slabs (less than nine inches) may be augmented through use of surface vibrators when approved by the Engineer. Consolidation of the concrete repair material from the top surface down, along with a leveling effect to assist the finishing operation, may be provided by vibrating screeds, plate or grid vibratory tampers, or vibrating roller screeds. The Contractor's Plan, including equipment selection and specifications, shall be submitted to the Contracting Officer for approval a minimum of five (5) days prior to concrete repair material placement using surface vibrating methods.

10. REMOVAL OF FORMS

Unless otherwise approved, forms shall not be removed sooner than the minimum time recommended by the manufacturer of the repair material or 48-hours whichever is greater.

Forms shall be removed only when the Engineer is present. Forms shall be removed in a manner to prevent damage to the concrete repair material. Supports shall be removed in a manner that will permit the repair material to take the stresses due to its own weight uniformly and gradually.

11. FINISHING FORMED SURFACES

All repaired surfaces shall be true and even, and shall be free of open or rough spaces, depressions or projections.

Immediately after the removal of forms:

All bulges, fins, form marks or other irregularities which in the judgment of the Engineer will adversely affect the appearance or function of the structure shall be

removed. All form bolts and ties shall be removed to a minimum depth of one (1) inch below the surface of the repair. The cavities produced by form ties and all other holes of similar size and depth shall be thoroughly cleaned and, after the interior surfaces have been kept continuously wet for at least three (3) hours, shall be carefully repaired with a compatible patching mortar or packed with a dry patching mortar mixed not richer than one (1) part cement and three (3) parts sand. Dry patching mortar shall be mixed in advance and allowed to stand without addition of water until it has reached the stiffest consistency that will permit placing. Manipulation of the mortar with a trowel during this period shall be performed as required to insure the proper consistency.

Holes resulting from form bolts or straps which pass through the wall shall be entirely filled with mortar to form a dense, well-bonded unit. The mortar shall be tamped into place with a rod slightly smaller than the hole being filled. The hardened mortar shall be sound and free from shrinkage cracks.

All repaired areas shall be cured as specified in Section 13.

12. FINISHING UNFORMED SURFACES

All exposed surfaces of the concrete repair material shall be accurately screeded to grade and finished to match adjacent surfaces, unless otherwise specified. Water shall not be sprinkled or in any manner added to the surface of conventional concrete mix repair material during finishing operations.

Proprietary repair materials shall be finished in accordance with the manufacturer's recommendations.

Joints and edges on unformed surfaces shall be shaped the same as adjacent or similar edges or corners of the structure being repaired.

13. CURING

The repair material shall be protected against premature surface drying, rainfall, and freezing for a minimum of 72-hours. For proprietary repair materials, the manufacturer's recommendations for curing shall be followed. Replacement concrete repair material shall be protected from drying and freezing for seven (7) days after placement.

If curing compound is used, it shall be non-solvent type and shall conform to ASTM C 309, Type 1-D, Class B, non-pigmented with a fugitive dye, unless otherwise specified. Curing compounds shall not be used if specifically prohibited by the proprietary repair material user guides.

14. REMOVAL OR REPAIR

When the repaired area is honeycombed, damaged or otherwise defective, the Contractor shall remove and replace the defective repair. The Engineer will

determine the required extent of removal, replacement and/or repair. Removal and repair activities shall be performed only when the Engineer is present.

15. CONCRETE REPAIR IN COLD WEATHER

For proprietary repair materials, the manufacturer's recommendation together with the requirements below will be followed.

For conventional concrete mix repair material, the requirements below shall be followed.

Concrete repairing in cold weather shall be performed in accordance with ACI 306, *Cold Weather Concreting*, of which some specific interpretations are set forth below.

Cold weather concrete repairing shall apply when the three-day average daily outdoor temperature at the job site is less than 40°F. When cold weather conditions exist on the job site, the following additional provisions shall apply:

- a. The temperature of the concrete repair material at the time of placing shall not be less than 55°F nor more than 90°F. The temperature of the mixing water shall not exceed 140°F when the cement is added nor shall aggregate temperature exceed 150°F.
- b. Concrete structures shall be immediately protected after placement of the concrete repair material. The temperature of the concrete repair material at the concrete surface shall be maintained at not less than 55°F nor more than 90°F during the seven (7) day protection period.
- c. Proper methods of covering, insulating, housing, or heating concrete structures shall be implemented.
- d. Exhaust flue gases from combustion heaters shall be vented to the outside of the heating enclosure.
- e. Following the completion of the protection period, the concrete repair material shall be allowed to cool gradually. The concrete repair material surface shall not have a temperature decrease in excess of 40°F in a 24-hour period.
- f. Concrete repair material placed during cold weather not meeting the cold weather definition above, shall be protected by proper methods for a minimum of 24-hours after placement.

16. CONCRETE REPAIR IN HOT WEATHER

For proprietary repair materials, the manufacturer's recommendation together with the requirements below shall be followed.

For replacement concrete repair material, the requirements below shall be followed.

For the purpose of this specification, hot weather is defined as any combination of the following conditions that may impair the quality of the freshly mixed and/or hardened concrete repair material by accelerating the rate of moisture loss and rate of cement hydration, or any other action that could contribute to detrimental results:

- High ambient temperature
- High concrete temperature
- Low relative humidity
- Wind velocity
- Solar radiation

Whenever the above conditions exist or when climatic conditions are such that the temperature of the concrete repair material may reasonably be expected to exceed 90°F at the time of delivery to the work site or during the placement operations, the following provisions shall apply:

- a. The Contractor shall maintain the temperature of the concrete repair material below 90°F during mixing, conveying, and placing.
- b. Exposed concrete repair material surfaces which tend to dry or set too rapidly shall be continuously moistened by means of fog sprays or other suitable means to maintain adequate moisture during the period between placement and finishing, and following finishing. Water shall not be sprinkled or added directly to the surface of the concrete repair prior to, or during, finishing.
- c. Finishing of slabs and other exposed or non-formed surfaces shall be started as soon as the condition of the concrete repair material allows and shall be completed without delay.
- d. Formed surfaces shall be kept completely and continuously moist for the duration of the curing period or until the application of the curing compound is completed.
- e. Concrete repair material surfaces, especially flat-work placed with large surface areas, shall be covered with wet burlap or other similar material as soon as the concrete repair material has sufficiently hardened and shall be kept continuously moist for a minimum of 24-hours for the initial curing period. This protective method shall be continued for the required curing period or until the application of curing compound is completed.
- f. Moist curing may be discontinued before the end of the curing period if white, or other color selected in Section 18, pigmented curing compound is applied immediately.
- g. Under extreme conditions of high ambient temperature, high concrete temperature, low relative humidity, wind velocity and exposure to solar radiation, the Engineer may (1) restrict placement to the most favorable time of day, (2) restrict the depth of layers to assure coverage of the previous layer while it will still respond readily to vibration, (3) suspend placement until conditions improve,

and (4) require removal of forms, repair, patching and re-application of wet curing by small areas at a time.

17. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established in the contract, concrete repair volume will be determined by computing the volume to the nearest 0.1 cubic foot between the neat lines shown on the drawings and the approved pay limit.

Method 2 For items of work for which specific unit prices are established in the contract, concrete repair volume will be determined by counting the number of pre-measured, pre-packaged units properly utilized to perform the approved repair. A pre-measured, pre-packaged unit is defined as a composite of all components and additives required to be mixed together before the repair material can be properly placed.

When only a part of a unit is needed to complete the filling of a repair void, it will be counted as one unit. Units required to fill voids outside the approved pay limits will not be counted for payment. Units mixed but not placed in a repair void due to Contractor's improper construction operation or management will not be counted.

Method 3 For items of work for which specific unit prices are established in the contract, concrete repair area will be determined by measuring the surfaces treated and computing the area to the nearest 0.1 square foot.

All Methods The following applies to all methods of measurement and payment:

Payment for concrete repair will be made at the contract unit price for the item. The payment for repair will constitute full compensation for all labor, materials, equipment, transportation, tools, forms, false-work, bracing and all other items necessary and incidental to the completion of the repair work.

Repair materials required to fill voids outside the neat lines or pay limits not directed or approved by the Engineer and resulting from excessive removal by the Contractor, damages caused by the Contractor activities, or improper construction operations as determined by the Contracting Officer will not be measured nor paid for under this item.

Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 18 of this specification.

REINFORCED CONCRETE PRESSURE PIPE CONDUITS

1. APPLICABILITY

Construction Specification 41 is applicable to the construction of principal spillway conduits appurtenant to earth dams using bedded or cradled reinforced concrete pressure pipe. It may also be applied to the construction of any type of reinforced concrete pipe conduit that crosses under or through an earth dam or other deep earth fill.

2. MATERIAL SPECIFICATIONS

The following specifications are complementary to Construction Specification 41:

- a. [Reinforced Concrete Pressure Pipe](#). Material Specification 541
- b. [Joint Sealing Compound](#). Material Specification 536
- c. [Preformed Expansion Joint Filler](#). Material Specification 535
- d. [Portland Cement Concrete for Bedding and Cradles](#). Construction Specification 31

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Line and grade of the conduit. Include statement in items of work that pipe shall be laid so that there is no reversal of grade between joints, unless shown on drawings.
- b. Details of the pipe bedding or cradle, including joint details.
- c. Excavation and backfill requirements, if applicable.
- d. Pay limits or actual limits for excavation.
- e. Details of wall fittings and other special pipe fittings.
- f. Special requirements for foundation preparation.
- g. Type of pipe.
- h. Size of pipe.
- i. Strength of pipe in terms of three-edge bearing load and internal pressure.
- j. Statement on acceptability for project use of pipe or pipe specimens tested in three-edge bearing test within the limits specified in Material Specification 541.
- k. Maximum allowable offset in alignment of interior pipe surface at joints, if tolerance is limited by cavitation hazard.

- l. Method of pressure test selected. See item 4b. Identify any variance from ASTM C 924 for air test criteria.
- m. Minimum joint length and minimum limiting angle of the joints according to definitions in Material Specification 541. Industry recommendation is to limit joint deflections to 1 1/2-inches.
- n. Type and class of expansion joint filler.
- o. Class of concrete for bedding or cradle and support blocks.
- p. Statement that metal strips covering the joints as specified in Section 4 are not required, if applicable. (If the conduit rests on bedrock so no appreciable movement will take place at the joints, metal cover strips generally will not be needed.)

4. DISCUSSION OF METHODS

a. Section 3, Laying the Pipe

- (1) Method 1 is the preferred method of stating the instructions for connecting pipe sections.
- (2) Method 2 is intended for use when special problems are anticipated or when the pipe to be furnished requires special methods of connection.

b. Section 5, Pressure Testing

- (1) Method 1 is considered adequate for principal spillway conduits that will operate under pressure intermittently at normal frequencies.
- (2) Method 2 may be required for principal spillway conduits that will operate under pressure for extended periods of time or at very frequent intervals.
- (3) Method 3 may be required where water is at a premium or unavailable, otherwise is not recommended because of potential size limitations and safety concerns.
- (4) Method 4 may be required for conduits that operate under pressure when large pipe diameters or other project restraints make method 2 and/or 3 difficult, expensive or unsafe to test.

c. Section 6, Measurement and Payment

- (1) Method 1 must be used when it is desired to base payment on the measurement of the laid length of the conduit.
- (2) Method 2 must be used when it is desired to base payment on the summation of the nominal laying lengths of the pipe sections used.

d. Sections 3 and 6

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete the following and left justify the remaining text.

(1) Section 3 "Use with Either Method"

(2) Section 6 "All Methods The following provisions apply to all methods of measurements and payment."

CONSTRUCTION SPECIFICATION

4I. REINFORCED CONCRETE PRESSURE PIPE CONDUITS

1. SCOPE

The work shall consist of furnishing and installing reinforced concrete pressure pipe conduits, fittings and accessories as shown on the drawings and/or specified herein.

2. MATERIALS

[Reinforced concrete pressure pipe, fittings and accessories](#) shall conform to the requirements of Material Specification 54I.

[Portland cement concrete for bedding and cradles](#) shall conform to the requirements of Construction Specification 3I for the specified class of concrete.

[Joint sealing compound](#) shall conform to the requirements of Material Specification 536.

[Preformed expansion joint filler](#) shall conform to the requirements of Material Specification 535.

[Filter Fabric](#) shall conform to Material Specification 592.

[Portland Cement Concrete for Bedding and Cradles](#) shall conform to Construction Specification 31.

3. LAYING THE PIPE

The pipe shall be set to the specified line and grade and temporarily supported on pre-cast concrete blocks or wedges. Concrete blocks and wedges used to temporarily support the pipe during placement of concrete bedding and/or cradle shall be of a class of concrete equal to or stronger than the concrete used to construct the bedding and/or cradle. Bell and spigot pipe shall be laid with the bells or grooves facing upstream unless otherwise specified in Section 7 or shown on the drawings. When pre-cast pipe risers and other similar pre-cast pipe structures are installed prior to pipe installation, pipe may be installed in the downstream direction with the belled end upstream. Adequate bell clearance in the subgrade/bedding shall be provided.

Just before each joint is connected the connecting surfaces of the bell and spigot or spigots and sleeve shall be thoroughly cleaned and dried, and the rubber gasket and the inside surface of the bell or sleeve shall be lubricated with a light film of soft vegetable soap compound (flax soap). The rubber gasket shall be stretched uniformly as it is placed in the spigot groove to insure a uniform volume of rubber around the circumference of the pipe.

Method 1 The joint shall be connected by means of a pulling or jacking force so applied to the pipe that the spigot enters squarely into the bell.

Method 2 The joint shall be connected in accordance with the manufacturer's instructions.

Use with Either Method When the spigot has been seated to within 1/2 inch of its final position, the position of the gasket in the joint shall be checked around the entire circumference of the pipe by means of a metal feeler gauge. In any case where the gasket is found to be displaced, the joint shall be disengaged and properly reconnected. After the position of the gasket has been checked, the spigot shall be completely pulled into the bell and the section of pipe shall be adjusted to line and grade.

4. FILLING JOINTS

Before the placement of the bedding or cradle, the exterior annular space between the ends of the pipe sections shall be cleaned and completely filled with joint sealing compound. Before the compound is applied, the surfaces against which it is to be placed shall be cleaned of all dust, lubricant and other substances that would interfere with a bond between the compound and the pipe. If recommended by the manufacturer of the compound, the concrete surfaces shall be coated with a primer in accordance with the manufacturer's recommendations. Primers shall be applied to the concrete surfaces only and shall not come in contact with the gasket or gasket sealing surfaces. Unless the compound or primer is specifically recommended for use on moist concrete, the surfaces shall be dry when it is applied.

The joint sealing compound shall be allowed to cure until it is sufficiently firm to prevent the entry of concrete or earth into the joint. Unless otherwise specified in Section 7 of this specification, prior to placing bedding or earth backfill (excluding concrete) containing particles larger than one-fourth inch in maximum dimension within 6 inches of the joint sealing compound, the compound shall be covered with a strip of 16-gage to 24-gage metal at least 2-inches wider than the space between the ends of the pipe sections. In lieu of metal strips, the joints shall be covered by a minimum of 2-foot wide, 4-ply thickness of filter fabric. Filter fabric shall be wrapped completely around the joint and overlapped a minimum of 12-inches at the top of the pipe. Lap shall be securely fastened to ensure filter fabric fits snugly during backfill operations. Filter fabric to be centered on the joint. Filter fabric shall conform to Material Specification 592, Table 2 Non-woven, Class II.

5. PRESSURE TESTING

Method 1 Pressure testing of the completed conduit will not be required.

Method 2 Prior to the placement of any concrete or earthfill around the conduit or filling of the pipe joints, the conduit shall be tested for leaks in the following manner: The ends of the conduits shall be plugged and a standpipe with a minimum diameter of two (2) inches shall be attached to the upstream plug. The conduit shall be braced at each end to prevent slippage. The conduit and the standpipe shall be filled with water. The water level in the standpipe shall be maintained a minimum of

10 feet above the invert of the upstream end of the conduit for a period of not less than two hours. Any leaks shall be repaired and the conduit shall be tested again as described above. The procedure shall be repeated until the conduit is watertight.

The pipe joints shall show no leakage. Damp spots developing on the surface of the pipe will not be considered as leakage.

Method 3 Prior to placement of any concrete or earthfill around the conduit or filling of the pipe joints, the conduit shall be air tested in accordance with ASTM C 924.

The conduit shall be braced on each end to prevent slippage. All end plugs used for the air test shall be capable of resisting the internal pressure and must be securely braced.

All testing equipment to be used shall be furnished by the Contractor and shall be inspected and approved by the Engineer. The pressure gauges used shall be graduated to read in increments of 0.1 psi and calibrated to provide accuracy within 10 percent plus or minus of the standard gauge. The Contractor has the option of pre-wetting the conduit or line prior to testing.

Any conduit that fails to pass this test must be repaired by a method satisfactory to the Engineer. After the repairs are made the conduit shall be re-tested until it passes the test requirements.

Method 4 Prior to the placement of concrete or earth backfill around the conduit joint to be tested or filling the pipe joints, the joint shall be tested in accordance to ASTM C 1103, *Standard Practice for Joint Acceptance Testing of Installed Pre-cast Concrete Sewer Line*. The test pressure shall specified in Section 7 of this specification. Any joints showing leaks shall be re-laid or repaired and the joint shall be re-tested. The procedure shall be repeated until the joint passes the test.

6. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established in the contract, the quantity of each size, type and class of pipe will be determined to the nearest 0.1 foot by measurement of the laid length of pipe along the invert centerline of the conduit. Payment for each size, type and class of reinforced concrete pressure pipe will be made at the contract unit price for that size, type and class of pipe. Such payment will constitute full compensation for furnishing, transporting and installing the pipe complete in place including accessories such as wall fittings, joint gaskets, coupling bands, sleeves or collars and all other items necessary and incidental to the completion of the work, except the special fittings and appurtenances listed separately in the bid schedule. Payment for each special fitting and appurtenance will be made at the contract price for that type and size of fitting or appurtenance.

Method 2 For items of work for which specific unit prices are established in the contract, the quantity of each size, type and class of pipe will be determined as the

sum of the nominal laying lengths of the pipe sections used. Payment for each size, type and class of reinforced concrete pressure pipe will be made at the contract unit price for that size, type and class of pipe. Such payment will constitute full compensation for furnishing, transporting and installing the pipe complete in place including accessories such as wall fittings, joint gaskets, coupling bands, sleeves or collars and all other items necessary and incidental to the completion of the work, except the special fittings and appurtenances listed separately in the bid schedule. Payment for each special fitting and appurtenance will be made at the contract price for that type and size of fitting and appurtenance.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 7 of this specification.

CONCRETE PIPE CONDUITS AND DRAINS

1. APPLICABILITY

Construction Specification 42 is applicable to all types of concrete pipe conduits except principal spillway conduits for earth dams or conduits under deep fills. It may be applied to culverts, to pipe collector systems in structure drains, to irrigation pipelines, or to portions of land drainage systems.

2. MATERIAL SPECIFICATIONS

The following specifications are complementary to Construction Specification 42:

- a. [Reinforced Concrete Pressure Pipe](#). Material Specification 541
- b. [Concrete Culvert Pipe](#). Material Specification 542
- c. [Concrete Irrigation Pipe, Drainage Pipe, and Drain Tile](#). Material Specification 543
- d. [Joint Sealing Compound](#). Material Specification 536
- e. [Preformed Expansion Joint Filler](#). Material Specification 535
- f. [Portland Cement Concrete for Bedding and Cradles](#). Construction Specification 31, [Concrete for Major Structures](#) or Construction Specification 32, [Structure Concrete](#).

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Line and grade of the conduit. Include statement in Section 11 that pipe shall be laid so that there is no reversal of grade between joints unless shown on the drawings.
- b. Details of concrete bedding or cradle, including class of concrete, joint details, and type of expansion joint filler.
- c. Details of earth, sand, or gravel bedding, including description and grading limits of the bedding material.
- d. Excavation and backfill requirements, if applicable.
- e. Pay limits or actual limits for excavation and backfill, if required.
- f. Special requirements for foundation preparation.
- g. Kind of pipe or tile by name and class. (See appropriate reference specifications.)
- h. Size of pipe or tile.

- i. Type of cement for pipe or tile if a certain type is necessary because of soil, water, or other environmental conditions.
- j. Strength of pipe, if not covered by reference specifications, in terms of three-edge-bearing load and internal pressure as appropriate.
- k. Type of joint and details of banded joints or other special joints.
- l. Details of wall fittings and other special fittings and appurtenances.
- m. Test pressure, if applicable.
- n. Method of measurement and payment if the standard specification includes more than one method.

4. DISCUSSION OF METHODS

a. Section 5a, Rubber Gasket Joint, Pressure Pipe.

(1) Method 1 is the preferred method of stating the instructions for connecting pipe sections.

(2) Method 2 is intended for use when special problems are anticipated or when the pipe to be furnished requires special methods of connection.

b. Section 9, Pressure Testing.

The methods are self-explanatory. The choice of method must be consistent with the function of the conduit and the required operating pressure.

c. Section 10, Measurement and Payment.

(1) Method 1 must be used when it is desired to base payment on the measurement of the laid length of the conduit.

(2) Method 2 must be used when it is desired to base payment on the summation of the nominal laying lengths of the pipe sections used.

d. Sections 5a, 9 and 10

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete the following and left justify the remaining text.

(1) Section 5a "Use with Either Method"

(2) Section 9 "For Methods 2, 3, 4" (Delete the entire paragraph when Methods 2, 3 and 4 are deleted.)

(3) Section 10 "All Methods The following provisions apply to all methods of measurements and payment."

CONSTRUCTION SPECIFICATION

42. CONCRETE PIPE CONDUITS AND DRAINS

1. SCOPE

The work shall consist of furnishing and installing concrete pipe or concrete drain tile and the necessary fittings as shown on the drawings.

2. MATERIALS

[Reinforced concrete pressure pipe](#) shall conform to the requirements of Material Specification 541 for the type and strength specified.

[Concrete culvert pipe](#) shall conform to the requirements of Material Specification 542 for the kind of pipe specified.

[Concrete irrigation pipe, drainage pipe and drain tile](#) shall conform to the requirements of Material Specification 543 for the kind of pipe or tile specified.

[Pipe fittings](#) shall conform to the requirements of the applicable pipe specifications.

[Sealing compound](#) for filling rubber gasket joints shall conform to the requirements of Material Specification 536.

[Hot-pour joint sealer](#) shall conform to the requirements of Material Specification 536.

[Cold-applied sealing compound](#) shall conform to the requirements of Material Specification 536.

[Preformed sealing compound](#) shall conform to the requirements of Material Specification 536.

[Joint packing](#) shall be commercial grade oakum.

[Preformed expansion joint filler](#) shall conform to the requirements of Material Specification 535.

[Portland Cement Concrete for Bedding and Cradles](#) shall conform to Construction Specification 31, [Concrete for Major Structures](#), or Construction Specification 32, [Structure Concrete](#).

3. LAYING AND BEDDING

Pipe and tile shall be laid to the line and grade shown on the drawings. Unless otherwise specified, belled pipe shall be laid with the bells or grooves facing upstream. When pre-cast pipe risers and other similar pre-cast pipe structures are installed prior to pipe installation, pipe may be installed in the downstream direction with the belled end upstream. Adequate bell clearance in the subgrade/bedding shall be provided.

- a. Concrete Cradles or Bedding. Pipe to be cradled or bedded on concrete shall be set to the specified line and grade and temporarily supported on pre-cast concrete blocks or wedges until the cradle or bedding concrete is placed. Concrete blocks or wedges used to temporarily support the pipe during placement of bedding or cradle shall be of a class of concrete equal to or stronger than that to be used in the bedding or cradle.
- b. Earth, Sand, or Gravel Bedding. The pipe shall be uniformly bedded throughout its entire length to the depth and in the manner specified on the drawings. The pipe shall be loaded sufficiently during backfilling around the sides to prevent displacement.

Perforated pipe shall be laid with the perforations down and oriented symmetrically about a vertical centerline. Perforations shall be clear of any obstructions when the pipe is laid.

Elliptical pipe and pipe with elliptical or quadrant reinforcement shall be laid so that the vertical axis, as indicated by markings on the pipe, is in a vertical position.

4. JOINTS

Pipe joints shall conform to the details shown on the drawings and to the requirements of Section 5 and 6 of this specification applicable to the type of joint specified. Except where unsealed joints are indicated, pipe joints shall be sound and watertight at the pressure specified.

5. JOINTING BELL AND SPIGOT PIPE

- a. Rubber Gasket Joint, Pressure Pipe. Just before the joint is connected the connecting surfaces of the spigot and the bell or coupling band, sleeve or collar shall be thoroughly cleaned and dried, and the rubber gasket and the inside surface of bell or coupling band, sleeve or collar shall be lubricated with a light film of soft vegetable soap compound (flax soap). The rubber gasket shall be stretched uniformly as it is placed in the spigot groove to insure a uniform volume of rubber around the circumference of the pipe.

Method 1 The joint shall be connected by means of a pulling or jacking force so applied to the pipe that the spigot enters squarely into the bell.

Method 2 The joint shall be connected in accordance with the manufacturer's recommendations.

Use with Either Method. When the spigot has been seated to within 1/2 inch of its final position, the position of the gasket in the joint shall be checked around the entire circumference of the pipe by means of metal feeler gauge. In any case where the gasket is found to be displaced, the joint shall be disengaged and properly reconnected. After the proper position of the gasket has been

confirmed, the spigot shall be completely pulled into the bell and the section of the pipe shall be adjusted to line and grade.

- b. Rubber Gasket Joints, Sewer and Culvert Pipe or Irrigation Pipe. The pipe shall be joined in accordance with the gasket manufacturer's recommendations except as otherwise specified.
- c. Mastic Sealed Joints. At the time of assembly the inside surfaces of the bell and the outside surfaces of the spigot shall be clean, dry and primed as recommended by the manufacturer of the sealing compound. A closely twisted gasket of joint packing of the diameter required to support the spigot at the proper grade and to make the joint concentric shall be made in one piece of sufficient length to pass around the pipe and lap at the top. The gasket shall be laid in the bell throughout the lower third of the circumference. The end of the spigot shall be laid in the bell throughout the lower third of the circumference. The end of the spigot shall be laid on the gasket and the spigot shall be fully inserted into the bell so that the pipe sections are closely fitted and aligned. The gasket then shall be lapped at the top of the pipe and thoroughly packed into the annular space between the bell and the spigot.
 - (1) Hot-Pour Joint Sealer. The sealing compound shall be heated to within the temperature range recommended by the manufacturer and shall not be overheated or subjected to prolonged heating. After the joint is assembled, with the pipe in its final location, a suitable joint runner shall be placed around the joint with an opening left at the top. Molten sealing compound shall be poured into the joint as rapidly as possible without entrapping air until the annular space between bell and spigot is completely filled. After the compound has set, the runner may be removed. Alternate joints may be poured before the pipe is lowered into the trench. In this case, the joint shall be poured with the pipe in a vertical position without the use of the runner. The compound shall have thoroughly set before the pipe is placed in the trench, and the pipe handled so as to cause no deformation of the joint during placement.
 - (2) Cold-Applied Sealing Compound. The annular space between bell and spigot shall be completely filled with the sealing compound. The compound shall be mixed on the job in accordance with the manufacturer's recommendations and in relatively small quantities so that setting will not be appreciable before application.
 - (3) Preformed Sealing Compound. Joint packing will not be required, except as recommended by the manufacturer of the sealing compound. Preformed strips or bands of the sealing compound shall be applied to the bell and spigot prior to assembly of the joint in accordance with the manufacturer's recommendations. Any compound extruded from the interior side of the joint during assembly shall be trimmed even with the interior surface of the pipe.

d. Cement Mortar Sealed Joints. Cement mortar for joints shall consist of one part by weight of portland cement and two parts by weight of fine sand with enough water added to produce a workable consistency. At the time of assembly the inside surface of the bell and the outside surface of the spigot shall be clean and moist.

(1) With Packing. A closely twisted gasket of joint packing of the diameter required to support the spigot at the proper grade and to make the joint concentric shall be made in one piece of sufficient length to pass around the pipe and lap at the top. The gasket shall be saturated with neat cement grout, laid in the bell throughout the lower third of the circumference and covered with mortar. The end of the spigot shall be fully inserted into the bell so that the pipe sections are closely fitted and aligned. A small amount of mortar shall be placed in the annular space throughout the upper two-thirds of the circumference. The gasket then shall be lapped at the top of the pipe and thoroughly packed into the annular space between the bell and the spigot. The remainder of the annular space then shall be filled completely with mortar and beveled off at an angle of approximately forty-five (45) degrees with the outside of the bell. If the mortar is not sufficiently stiff to prevent appreciable slump before setting, the outside of the joint thus made shall be wrapped with cheesecloth. After the mortar has set slightly, the joint shall be wiped inside the pipe. In pipe too small for a person to work inside, wiping may be done by dragging an approved swab through the pipe as the work progresses.

(2) Without Packing. The lower portion of the bell shall be filled with stiff mortar of sufficient thickness to make the inner surface of the abutting sections flush. The spigot end of the pipe to be joined shall be fully inserted into the bell so that the sections are closely fitted and aligned. The remaining annular space between the bell and spigot shall then be filled with mortar and the mortar neatly beveled off at an angle of approximately forty-five (45) degrees with the outside of the bell. After the mortar has set slightly, the joint shall be wiped inside the pipe. In pipe too small for a person to work inside, wiping may be done by dragging and approved swab through the pipe as the work progresses.

e. Unsealed Joints. When unsealed joints are specified, they shall conform to the details shown on the drawings.

6. JOINTING TONGUE AND GROOVE PIPE

a. Cement Mortar Sealed Joint. Mortar shall be as specified for bell and spigot joints. The tongue end of the section being placed shall be covered with mortar and firmly pressed into the groove of the laid section in such manner that the tongue fits snugly and truly in the groove and that mortar is squeezed out both on the interior and exterior of the joint. Care shall be taken that no mortar falls from the groove end during the abutting operation. Immediately after the pipe sections have been abutted, exposed external surface mortar shall be pressed into the

joint and any excess mortar removed, after which the interior surface of the joint shall be carefully pointed and brushed smooth, and all surplus mortar removed.

- b. Mastic Sealed Joints. Strips or bands of preformed sealing compound shall be applied to the tongue and groove prior to assembly of the joint in accordance with the manufacturer's recommendations. Any compound extruded from the interior side of the joint during assembly shall be trimmed even with the interior surface of the pipe.
- c. Rubber Gasket Joints. The pipe shall be joined in accordance with the gasket manufacturer's recommendations except as otherwise specified.
- d. Unsealed Joints. When unsealed joints are specified, they shall conform to the details shown on the drawings.

7. BANDING

When external mortar bands are specified, they shall conform to the details shown on the drawings.

8. CURING MORTAR JOINTS AND BANDS

The external surfaces of mortar joints shall be covered with moist earth, sand, canvas, burlap or other approved materials and shall be kept moist for 10-days or until the pipe is backfilled. Earth backfilling operations shall not begin until 24-hours after joints are finished.

Water shall not be turned into the conduit within 24 hours after the joints are finished. Hydrostatic pressure shall not be applied to the conduit prior to 14 days after the joints are finished.

9. PRESSURE TESTING

Method 1 Pressure testing of the completed conduit will not be required.

Method 2 Prior to the placement of concrete or earth backfill around the conduit, the conduit shall be tested for leaks in the following manner: The ends of the conduits shall be plugged and a standpipe with a minimum diameter of two (2) inches shall be attached to the upstream plug. The conduit shall be braced at each end to prevent slippage. The conduit and the standpipe shall be filled with water. The water level in the standpipe shall be maintained a minimum of 10 feet above the invert of the upstream end of the conduit for a period of not less than two hours. Any leaks shall be repaired and the conduit shall be re-tested as described above. The procedure shall be repeated until the conduit is watertight.

Method 3 Prior to the placement of concrete or earth fill around the conduit, the conduit shall be tested at the specified test pressure for a period of at least 2 hours.

Any leaks shall be repaired and the conduit shall be re-tested. The procedure shall be repeated until the conduit is watertight.

Method 4 Prior to the placement of concrete or earth backfill around the conduit joint to be tested, the joint shall be tested in accordance to ASTM C 1103, *Standard Practice for Joint Acceptance Testing of Installed Pre-cast Concrete Pipe Sewer Lines*. Any joints showing leaks shall be re-laid or repaired and the joint shall be re-tested. The procedure shall be repeated until the joint passes the test.

For Methods 2, 3, and 4 The pipe joints shall show no leakage. Damp spots developing on the surface of the pipe will not be considered as leaks.

10. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established in the contract, the quantity of each kind, size, and class of pipe or tile will be determined to the nearest 0.1 foot by measurement of the laid length along the invert centerline of the conduit. Payment for each kind, size, and class of pipe or tile will be made at the contract unit price for that kind, size, and class. Such payment will constitute full compensation for furnishing, transporting and installing the pipe or tile complete in place.

Method 2 For items of work for which specific unit prices are established in the contract, the quantity of each kind, size, and class of pipe or tile will be determined as the sum of the nominal laying lengths of the sections used. Payment for each kind, size, and class of pipe or tile will be determined as the sum of the nominal laying lengths of the sections used. Payment for each kind, size, and class of pipe or tile will be made at the contract unit price for that kind, size, and class. Such payment will constitute full compensation for furnishing, transporting and installing the pipe or tile complete in place.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 11 of this specification.

CLAY PIPE

1. APPLICABILITY

Construction Specification 43 is applicable to all types of clay pipe conduits. Application to pipe collector systems in structure drains or to portions of land drainage systems is applicable.

2. MATERIAL SPECIFICATIONS

The following specifications are complementary to Construction Specification 43:

- a. [Clay Pipe and Drain Tile](#). Specification 544
- b. [Sealing Compound for Joints in Concrete and Concrete Pipe](#). Specification 536

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Line and grade of the conduit. Include statement in items of work that pipe shall be installed in a manner that no reversal of grade between joints occurs, unless shown on the drawings.
- b. Details of the bedding, including description and grading limits of the bedding material.
- c. Excavation and backfill requirements, if applicable.
- d. Pay limits or actual limits for excavation and backfill, if required. When excavation requirements need to be performed to be in compliance with safety requirements, state clearly when those volumes are included or not in the pay limits.
- e. Kind and class of pipe or tile.
- f. Size(s) of pipe or tile.
- g. Type of joint and details of special joints.
- h. Details of wall fittings and other special fittings and appurtenances.
- i. Pressure testing requirements, if applicable.
- j. Method of measurement and payment if the standard specification includes more than one method.

4. DISCUSSION OF METHODS

a. Section 6, Measurement and Payment

- (1) Method 1 must be used when it is desired to base payment of the measurement of the laid length of the conduit.
- (2) Method 2 must be used when it is desired to base payment on the summation of the nominal laying lengths of the pipe conduit.

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

43. CLAY PIPE

1. SCOPE

The work shall consist of furnishing and installing clay pipe and/or clay drain tile and the necessary fittings as shown on the drawings.

2. MATERIALS

Pipe, drain tile, and fittings shall conform to the requirements of Material Specification 544 for the kind of pipe or tile specified.

Sealing compound for filling rubber gasket joints shall conform to the requirements of Material Specification 536.

Compression joints using resilient materials shall conform to the requirements of ASTM C 425.

Non-pour joint sealer shall conform to the requirements of Material Specification 536.

Cold-applied sealing compound shall conform to the requirements of Material Specification 536.

Joint packing shall be commercial grade oakum.

3. LAYING AND BEDDING

Pipe and tile shall be installed to the line and grade shown on the drawings. Each pipe section shall be installed with the bell end upstream.

The pipe shall be firmly and uniformly bedded throughout its entire length to the depth and in the manner specified on the drawings. The pipe shall be loaded sufficiently during backfilling around the sides to prevent uplift of the pipe and the development of voids between the pipe and bedding.

Perforated pipe and tile shall be laid with the perforations down and oriented symmetrically about the vertical centerline. Perforations shall be clear of any obstructions when the pipe is installed.

4. JOINTS

Pipe joints shall conform to the details shown on the drawings, except where unsealed joints are indicated, and shall be sound and watertight at the pressures specified.

- a. Rubber gasket joints shall be assembled in accordance with the gasket manufacturer's recommendations, except as otherwise specified.

- b. Compression joints using resilient materials shall be assembled in accordance with the manufacturer's recommendations.
- c. Mastic Sealed Joints. At the time of pipe assembly, the inside surfaces of the bell and the outside surfaces of the spigot shall be clean, dry and primed as recommended by the manufacturer of the sealing compound. A closely twisted gasket of joint packing of the diameter required to support the spigot at the proper grade and to make the joint concentric shall be made in one piece of sufficient length to pass around the pipe and lap at the top of the pipe and be thoroughly packed into the annular space between the bell and the spigot.
 - (1) Hot-pour Joint Sealer. The sealing compound shall be heated to within the temperature range recommended by the manufacturer and shall not be overheated or subjected to prolonged heating. After the joint is assembled, with the pipe in its final location, a suitable joint runner shall be placed around the joint with an opening left at the pipe top. Molten sealing compound shall be poured into the joint as rapidly as possible without entrapping air until the annular space between bell and spigot is completely filled. After the compound has set, the runner may be removed. Alternate joints may be poured before the pipe is lowered into the trench. When this installation procedure is used, the joint shall be poured with the pipe in a vertical position without the use of a runner. The compound shall have thoroughly set before the pipe is placed in the trench, and the pipe shall be handled so as to cause no deformation of the joint during placement.
 - (2) Cold-Applied Sealing Compound. The annular space between bell and spigot shall be completely filled with the sealing compound. The compound shall be mixed on the job in accordance with the manufacturer's recommendations and in relatively small quantities so that setting will not be appreciable before application.
 - (3) Preformed Sealing Compound. Joint packing will not be required, except as recommended by the manufacturer of the sealing compound. Preformed strips or bands of the sealing compound shall be applied to the bell and spigot prior to assembly of the joint in accordance with the manufacturer's recommendations. Any compound extruded from the interior side of the joint during assembly shall be trimmed even with the interior surface of the pipe.
- d. Cement Mortar Sealed Joints. Cement mortar for joints shall consist of one part by weight of portland cement and two parts by weight of fine sand with; adequate water added to produce a workable consistency. At the time of assembly the inside surface of the bell and the outside surface of the spigot shall be clean and moist.
 - (1) With Packing. A closely twisted gasket of joint packing of the diameter required to support the spigot at the proper grade and to make the joint concentric shall be made in one piece of sufficient length to pass around the

pipe and lap at the pipe top. The gasket shall be saturated with neat cement grout, laid in the bell throughout the lower third of the circumference and covered with mortar. The end of the spigot shall be fully inserted into the bell so that the pipe sections are closely fitted and aligned. A small amount of mortar shall be placed in the annular space throughout the upper two-thirds of the circumference. The gasket then shall be lapped at the top of the pipe and thoroughly packed into the annular space between the bell and the spigot. The remainder of the annular space shall then be filled completely with mortar and beveled off of an angle of approximately forty-five (45) degrees with the outside of the bell. If the mortar is not sufficiently stiff to prevent appreciable slump before setting, the outside of the joint thus made shall be wrapped with cheesecloth. After the mortar has set slightly, the joint shall be wiped inside the pipe. In pipe too small for a person to work inside, wiping may be accomplished by dragging an approved swab through the pipe as the work progresses.

(2) Without Packing. The lower portion of the bell shall be filled with stiff mortar of sufficient thickness to make the inner surface of the abutting sections flush. The spigot end of the pipe to be jointed shall be fully inserted into the bell so that the sections are closely fitted and aligned. The remaining annular space between the bell and spigot shall be then filled with mortar and the mortar neatly beveled-off at an angle of approximately forty-five (45) degrees with the outside of the bell. After the mortar has set slightly, the joint shall be wiped inside the pipe. In pipe too small for a person to work inside, wiping may be accomplished by dragging an approved swab through the pipe as the work progresses.

e. Unsealed Joints. When unsealed joints are specified, they shall conform to the details shown on the drawings.

5. CURING MORTAR JOINTS

The external surfaces of mortar joints shall be covered with moist earth, sand, canvas, burlap or other approved materials and shall be kept moist for ten (10) days or until the pipe is backfilled.

Water shall not be turned into the conduit within 24 hours after the joints are finished.

6. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established in the contract, the quantity of each kind, size, and class of pipe or tile will be determined to the nearest foot by measurement of the laid length along the invert centerline of the conduit. Payment for each kind, size, and class of pipe or tile will be made at the contract unit price for that kind, size, and class. Such payment will constitute full

compensation for furnishing, transporting and installing the pipe or tile complete in place.

Method 2 For items of work for which specific unit prices are established in the contract, the quantity of each kind, size and class of pipe or tile will be determined as the sum of the nominal laying lengths of the sections satisfactorily installed. Payment for each kind, size and class of pipe or tile will be made at the contract unit price for that kind, size and class. Such payment will constitute full compensation for furnishing, transporting and installing the pipe or tile complete in place.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 7 of this specification.

CORRUGATED POLYETHYLENE TUBING

1. APPLICABILITY

Construction Specification 44 is applicable for use for land drainage and drains for embankments, foundations, structures, and other conduit systems.

2. MATERIAL SPECIFICATIONS

The following specification is complementary to Construction Specification 44:

- a. [Corrugated Polyethylene Tubing](#). Specification 548

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Line and grade of tubing. Include in the Items of Work and Construction Details, Section 9, any applicable limitations or restrictions on the grade of the tubing, such as, reverse grades will not be acceptable.
- b. Details of the trench bottom.
- c. Details of the bedding, including description and grading limits of the bedding material.
- d. Describe in Section 9 the range of over-excavation that will be permitted without corrective measures.
- e. Diameter(s) of the tubing and interior finish (corrugated or smooth wall).
- f. Describe any special filter envelope for tubing, if required.
- g. Type of joint and details for any special joints.
- h. Details of special fittings and appurtenances.
- i. Details for connections with other appurtenances and/or existing structures.
- j. Details and specifications for nylon sock, when required.

4. DISCUSSION OF METHODS

- a. Section 8, Measurement and Payment

(1) Method 1 includes all excavation and earth backfill to install the pipe.

(2) Method 2 is intended for use when separate payment items are identified for earthwork.

When a nylon sock or other special filter material is an installation requirement, mention the item in Section 9 of this specification as an included item for measurement and payment, if it is not a separate item in the bid schedule.

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

Note: At the present time, ASTM does not have a standard for double wall or ribbed pipe, or the tubing covered by AASHTO M252 and M294.

CONSTRUCTION SPECIFICATION

44. CORRUGATED POLYETHYLENE TUBING

1. SCOPE

The work shall consist of furnishing and installing tubing and the necessary fittings and appurtenances as shown on the drawings and as outlined in this specification.

2. MATERIALS

[Corrugated polyethylene tubing and fittings](#) shall conform to the material requirements as outlined in Material Specification [548](#).

When perforations are specified, the water inlet area shall be a minimum of one (1) square inch per lineal foot of tubing. The inlets shall be either circular perforations or slots equally spaced along the length and circumference of the tubing. Unless otherwise specified, circular perforations shall not exceed 3/16-inch in diameter, and slot perforations shall not be more than 1/8-inch wide.

Geotextile filter socks, when required, shall meet the material requirements outlined in Section 9 of this specification.

Granular bedding material, when specified, shall conform to the requirements specified in Section 9 of this specification.

The tubing shall be appropriately marked with ASTM or AASHTO designation.

3. HANDLING AND STORAGE

Tubing shall be delivered to the job site and handled by means which provides adequate support to the tubing and does not subject it to undue stresses or damage. When handling and placing corrugated polyethylene tubing, care shall be taken to prevent impact blows, abrasion damage, and gouging or cutting (by metal edges and/or surfaces or rocks). All special handling requirements of the manufacturer shall be strictly observed. Special care shall be taken to avoid impact when the pipe must be handled at temperatures of 40° Fahrenheit or less.

Tubing shall be stored on a relatively flat surface so that the full length of the tube is evenly supported. Unless the tube is specifically manufactured to withstand exposure to ultraviolet radiation, it shall be covered with an opaque material when stored outdoors for a period of fifteen days or longer.

4. EXCAVATION

Unless otherwise specified or approved by the Engineer, excavation for and subsequent installation of each tube line shall begin at the outlet end and progress upgrade.

The trench or excavation for the tubing shall be constructed to the lines, depths, cross sections, and grade shown on the drawings, specified in Section 9 of this specification or as approved by the Engineer.

Trench shields, shoring and bracing, or other suitable methods necessary to safeguard the Contractor's employees and the works of improvement, and to prevent damage to the existing improvements shall be furnished, placed, and subsequently removed by the Contractor.

5. PREPARING THE TUBING BED AND BLINDING THE TUBING

When a granular filter or envelope is specified, the filter or envelope materials shall be placed in the bottom of the trench just prior to the laying of the tubing. The tubing shall then be laid and the filter and envelope material placed to a depth over the top of the tubing of not less than as shown on the drawings or as specified in Section 9 of this specification.

When a granular filter or envelope is not specified, the bottom of the trench shall be shaped to form a semicircular or trapezoidal groove in its center. This groove shall provide support for not less than one-fourth of the outside circumference of the tubing. After the tubing is placed in the excavated groove, it shall be capped with friable materials from the sides of the trench. The friable material shall be placed around the tubing, completely filling the trench to a depth of not less than three (3) inches over the top of the tubing. For materials to be suitable it must not contain hard clods, rocks, frozen soil, or fine material which will cause a silting hazard to the drain. Tubing placed during any day shall be blinded (place required soil material around and over pipe) and temporarily capped prior to the completion of construction activities for that day.

6. PLACEMENT AND JOINT CONNECTIONS

All tubing shall be installed to grade as shown on the drawings.

After placement of the tubing in the trench and blinding, sufficient time shall be allowed for the tubing to adapt to the soil temperature prior to backfilling.

Maximum allowable stretch of the tubing shall be five (5) percent. Special precautions must be implemented on hot, bright days to insure that the stretch limit is not exceeded, and excessive deflection does not occur as a result of installation procedures, including backfill operations.

Unless otherwise specified in Section 9 of this specification or shown on the drawings, connections will be made with manufactured junctions comparable in strength with the specified tubing. All split fittings shall be securely fastened with nylon cord or plastic zip-ties before any backfill is placed. All buried ends shall be supplied with end caps unless otherwise approved by the Engineer.

7. BACKFILLING

Unless otherwise specified in Section 9 of this specification, the backfilling of the trench shall be as shown on the drawings and completed as rapidly as is consistent with the soil conditions.

Automatic backfilling machines may be used only when approved by the Engineer. Backfill shall extend above the ground surface and be well rounded and centered over the trench.

8. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established in the contract, the quantity of each kind and size of tubing will be determined to the nearest foot of length measured along the centerline of the installed tubing. Payment for each kind and size of tubing will be made at the contract unit price for that kind and size of tubing. Such payment will constitute full compensation for all labor, equipment, tools, and all other items necessary and incidental to furnishing, transporting and installing the tubing, including excavation, shoring, geotextile or granular filter (when specified), backfill and all fittings, appurtenances and other items required to complete the work. Payment for appurtenances listed separately in the bid schedule will be made at the contract unit price(s) for that size and type of appurtenance listed.

Method 2 For items of work for which specific unit prices are established in the contract, the quantity of each kind, size, and class of tubing will be determined to the nearest foot by measurement of the laid length along the crown centerline of the tubing. Payment for each kind, size, and class of tubing will be made at the contract unit price for the kind, size, and class. Such payment will constitute full compensation for furnishing, transporting, and installing the tubing including shoring, all fittings, thrust blocks, appurtenances, and other items necessary and incidental to the completion of the work. Payment for appurtenances listed separately in the bid schedule will be made at the contract prices for those items.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 9 of this specification.

PLASTIC PIPE

1. APPLICABILITY

Construction Specification 45 is applicable for the use of plastic pipe conduits, except corrugated polyethylene tubing, see Construction Specification 44.

2. MATERIAL SPECIFICATION

Material Specification 547 is complementary to Construction Specification 45.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Line and grade of the conduit.
- b. Details of the bedding and shape and placement requirements.
- c. Description of the bedding materials and grading limits, if needed.
- d. Excavation requirements. Provide pay limits or actual limits for excavation, minimum trench width, if applicable and any special considerations necessary in case of unstable trench bottom and/or walls, safety, etc.
- e. Backfill requirements. Provide pay limits or actual limits of backfill, compaction requirements or other special methods of performing and controlling backfill, including the kind of material, as appropriate.
- f. Specify industry (ASTM or AWWA) material standards and/or specifications that the pipe material is required to meet, as applicable.

The designer may require a specific type of pipe by listing in Section 14 of this construction specification, and/or the appropriate reference specifications. The designer must be prepared to evaluate and accept pipe meeting other references that equal or exceed the minimums specified when proposed by the contractor or supplier. NRCS will maintain a limited list of reference specifications in NRCS offices for use of design and construction personnel.

- g. Specify the salient features of the pipe, which are required to meet the intent of the design.
 - (1) Size (diameter, include ID or OD if critical) and type of plastic (PE, HDPE, ABS, PVC 1120, etc.).
 - (2) Schedule, SDR or DR, pressure class and/or pressure rating, as appropriate.
 - (3) Perforation requirements if different from Material Specification 547.
- h. Type of joint by referring to a reference specification or details of any specific joint requirements.

- i. Details of special fittings, when applicable.
- j. Type of protective coatings for special fittings and appurtenances, when applicable (include field repair requirements).
- k. Pressure testing specifications, including rate of filling requirements, if applicable. The test pressure specified should not be less than the normal operating pressure together with the duration of the test with the allowable pressure change that will be acceptable.
- l. Specify and detail concrete thrust blocks, encasement, and anchors where applicable. Requirements for concrete encasement and for thrust blocks if other than Construction Specification [32, Structure Concrete](#), Class 3000M.
- m. Methods of measurement and payment.

4. DISCUSSION OF METHODS

a. Section 12, Pressure Testing

The methods are self-explanatory. The choice of method must be consistent with the function of the conduit and the required operating pressure.

b. Section 13, Measurement and Payment

The methods are self-explanatory.

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

5. DISCUSSION

This specification is written to include cast iron pipe sizes, iron pipe sizes (IPS), sewer pipe, pressure pipe, water pipe, drainpipe, and plastic irrigation pipe (PIP).

In addition to the ductile iron and cast iron fittings, one piece, injection molded, gasketed PVC plastic fittings are available for PVC pipe. These fitting are available for sewer pipe sizes 4 inches to 15 inches, for IPS-PVC pipe sizes 1.5 inches to 8 inches, and for AWWA Standard C900 pipes which are compatible with cast iron pipe sizes 4 inches to 8 inches.

CONSTRUCTION SPECIFICATION

45. PLASTIC PIPE

1. SCOPE

The work shall consist of furnishing and installing plastic pipe, except corrugated polyethylene tubing, and the necessary fittings and appurtenances as shown on the drawings or as specified herein.

2. MATERIAL

Pipe, fittings, and gaskets shall conform to the requirements of Material Specification 547 and as specified in Section 14 of this specification or as shown on the drawings.

Perforated pipe shall conform to the requirements of Material Specification 547 and as specified in Section 14 of this specification or as shown on the drawings.

Unless otherwise specified, concrete shall conform to the requirements of Construction Specification 32, Structure Concrete, and Section 8 of this specification.

Unless otherwise specified, earth backfill shall conform to the requirements of Construction Specification 23, Earthfill.

Unless otherwise specified, drainfill shall conform to the requirements of Construction Specification 24, Drainfill.

3. HANDLING AND STORAGE

Pipe shall be delivered to the job site and handled by means which provide adequate support to the pipe and do not subject it to undue stresses or damage. When handling and placing plastic pipe, care shall be taken to prevent impact blows, abrasion damage, and gouging or cutting (by metal edges and/or surfaces or rocks). All special handling requirements of the manufacturer shall be strictly observed. Special care shall be taken to avoid impact when the pipe must be handled at temperatures of 40° Fahrenheit or less.

Pipe shall be stored on a relatively flat surface so that the barrels are evenly supported. Unless the pipe is specifically manufactured to withstand exposure to ultraviolet radiation, it shall be covered with an opaque material when stored outdoors for period of fifteen days or longer.

4. EXCAVATION

Excavation shall be in accordance with Construction Specification 21, Excavation, and Section 14 of this specification or as shown on the drawings.

The pipe foundation shall be excavated a minimum of four inches lower than the pipe grade shown on the drawings or staked in the field whenever bedrock,

boulders, cobbles, or other materials that may cause pipe damage are encountered at planned pipe grade.

5. LAYING THE PIPE

Plastic pipe conduits complete with fittings and other related appurtenances shall be installed to the lines and grades shown on the drawings or specified in Section 14 of this specification. The pipe shall be installed so that there is no reversal of grade between joints unless otherwise shown on the drawings. The pipe shall not be dropped or dumped on the bedding or into the pipe trench. The ground surface near the pipe trench shall be free of loose rocks and stones greater than one (1) inch in diameter to ensure that rock will not be displaced and impact the pipe.

Just prior to placement, each pipe section shall be inspected to insure that all foreign materials are removed from the inside of the pipe. The pipe ends and the couplings shall be free of foreign material when assembled. At the completion of a work shift, all open ends of the pipeline shall be temporarily closed off by a suitable cover or plug.

Care shall be taken to prevent distortion and damage during periods of hot or cold weather. During unusually hot weather (daytime high temperatures greater than 90° F), the pipe assembled in the trench shall be lightly backfilled or shaded to keep it as near to ground temperature as possible until final backfill is placed. Backfill operations should be performed during daily construction periods when the ground temperature and the temperature of the pipe does not vary more than 40° F.

Perforated pipe shall be installed with the perforations down and oriented symmetrically about the vertical centerline. Perforations shall be clear of any obstructions on the inside and outside of the pipe when the pipe is approved by the Engineer for backfill.

During installation, the pipe shall be firmly and uniformly bedded throughout its entire length, to the depth and in the manner specified in Section 14 of this specification or as shown on the drawings. Bell-holes shall be placed in bedding material under bells, couplings and other fittings to assure the pipe is uniformly supported throughout its entire length. Blocking or mounding beneath the pipe to bring the pipe to final grade will not be permitted.

6. PIPE EMBEDMENT

Earth Bedding. The pipe shall be firmly and uniformly placed on compacted earthfill bedding or an in-place earth material bedding of ample bearing strength to support the pipe without noticeable settlement. The earth material on which the pipe is placed shall be of uniform density to prevent differential settlement.

Unless otherwise specified, a groove that closely conforms to the outside surface of the pipe shall be formed in the bedding. The depth of the groove shall be equal to or greater than 0.3 of the pipe diameter.

Earth bedding shall be compacted to a density not less than adjacent undisturbed in-place earth materials or be compacted earth backfill. Earthfill materials used for compacted earth bedding shall be free of rocks or stones greater than one (1) inch in diameter and earth clods greater than two (2) inches in diameter. The pipe shall be loaded sufficiently during the compaction of bedding under the haunches and around the sides of the pipe to prevent displacement from its final approved placement.

Sand, Gravel, or Crushed Rock Bedding. When sand, gravel, or crushed rock bedding is specified, the pipe shall be firmly and uniformly placed on the bedding material. Material for bedding shall not exceed one (1) inch in diameter. Unless otherwise specified in Section 14 of this specification or shown on the drawings, the coarse-grained bedding material shall be carefully placed and compacted to a depth equal to or greater than 0.3 of the diameter of the pipe above the bottom of the pipe. The pipe shall be loaded sufficiently during backfilling and compaction around the sides to prevent displacement of the pipe from its final approved placement.

Pipe Encased in Drainfill. The pipe shall be firmly and uniformly placed on a bedding of specified drainfill. Drainfill shall be placed and compacted as specified in Section 14 of this specification or as shown on the drawings to form a continuous uniform support around the entire circumference of the pipe. The pipe shall be loaded sufficiently during backfilling around the sides and during compaction to prevent displacement of the pipe.

7. BACKFILL

a. Initial Backfill

Unless otherwise specified, initial backfill to six (6) inches above the top of the conduit is required. Earth haunching and initial backfill materials shall consist of soil material that is free of rocks, stones or hard clods greater than one (1) inch in diameter. Coarse backfill material shall be the specified sand, gravel, crushed rock or drainfill material.

Initial backfill shall be placed in two (2) stages. The first stage (haunching) backfill is placed to the pipe spring line (center of pipe). The second stage backfill is placed to six (6) inches above the top of the pipe. The first stage material shall be worked carefully under the haunches of the pipe to provide continuous support throughout the entire pipe length. The haunching backfill material shall be placed in layers approximately six (6) inches maximum thickness and compacted as specified in Section 14 of this specification or as shown on the drawings. During compaction operations, care shall be taken to ensure that the tamping or vibratory equipment does not come in contact with the pipe and the pipe is not deformed or displaced.

When pressure testing is not specified, the pipe shall be covered with a minimum of six (6) inches of backfill material as soon as possible following assembling of the pipe in the trench, but not later than within the same day that placement has

occurred. When pressure testing is specified, sufficient backfill material shall be placed over the pipe to anchor the conduit against movement during pressure testing activities.

b. Final Backfill

Final backfill shall consist of placing the remaining material required to complete the backfill from the top of the initial backfill to the ground surface, including mounding at the top of the trench. Final backfill material within two (2) feet of the top of the pipe shall be free of debris or rocks larger than three (3) inches nominal diameter. Coarse backfill materials shall be the specified sand, gravel, crushed rock or drainfill. Final backfill shall be placed in approximately uniform, compacted layers. Final backfill compaction requirements shall be as specified in Section 14 of this specification or as shown on the drawings.

Vehicles or construction equipment shall not be allowed to cross the pipe until the minimum earth cover and required density as specified in Section 14 of this specification has been obtained.

8. PIPE ENCASEMENT IN CONCRETE

Concrete encasement shall be carefully placed to form a continuous uniform support around the entire circumference of the pipe as specified in Section 14 of this specification or as shown on the drawings. Pipes encased in concrete shall be securely anchored to prevent movement of the pipe during concrete placement. A clear distance of 1 1/2 inches shall be maintained between the pipe and the reinforcing steel.

The concrete for the encasement shall conform to the requirements of Construction Specification [32, Structure Concrete](#), for Class 3000M concrete, unless otherwise specified.

9. JOINTS

Unless otherwise specified in Section 14 of this specification or shown on the drawings, joints shall be either bell and spigot type with elastomeric gaskets, coupling type, solvent cement bell and spigot, or jointed by butt heat fusion. When a lubricant is required to facilitate joint assembly, it shall be a type having no deleterious affect on the gasket or pipe materials.

Pipe joints shall be watertight at the pressures specified except where unsealed joints are indicated.

Pipe shall be installed and joined in accordance with the manufacturer's recommendations. Laying deflections and joint fitting or stab depths shall be within the manufacturer's recommended tolerances.

When solvent cement joints are specified for PVC or ABS pipe and fittings, they shall be made in accordance with the following ASTMs and the related appendix of each ASTM; D 2855 for PVC pipe and fittings, and D 2235 for ABS pipe and fittings.

Flanged, banded, heat-fusion, or elastomeric-sealed mechanical joints shall be used when joining polyethylene (PE) and high density polyethylene (HDPE) pipe and fittings, unless otherwise specified in Section 14 of this specification or as shown on the drawings.

Pipe ends shall be cut square and be de-burred to provide uniform, smooth surfaces for the jointing process. Reference marks shall be placed on the spigot ends to assist in determining when proper seating depth has been achieved within the joint.

10. FITTINGS

Unless otherwise specified, steel fittings, valves, and bolted connections shall be painted or coated as recommended by the manufacturer.

Fittings for non-pressure pipe shall be of the same or similar materials as the pipe and shall provide the same durability, watertightness, and strength as the pipe, unless otherwise specified.

11. THRUST BLOCKS AND ANCHORS

When specified, concrete thrust blocks and anchors shall be installed as shown on the drawings or specified in Section 14 of this specification.

The concrete for the thrust blocks and anchors shall conform to the requirements of Construction Specification 32, [Structure Concrete](#), for Class 3000M concrete, unless otherwise specified in Section 14 of this specification.

The thrust block cavity shall be hand dug into undisturbed soil or previously placed compacted backfill. The cavity shall be formed with soil or wood to hold the freshly place concrete without displacement until an initial set has occurred.

When excavation beyond the designated trench widths and depths as shown on the drawings or specified in Section 14 of this specification occurs at locations where installation of concrete thrust blocks is required, the Contractor shall install an alternative thrust block provision. The concrete thrust block shall have a thickness of one pipe diameter and a contact face area as shown on the drawings or specified in Section 14 of this specification which shall be formed against the pipe. Backfill shall be placed on all sides of the thrust block and to the sides of the excavation and compacted as specified for initial backfill.

12. PRESSURE TESTING

Method 1 Pressure testing of the completed conduit is not required.

Method 2 The conduit shall be tested for leaks in the following manner:

a. Prior to pressure testing:

- (1) Joints of the assembled pipeline shall be allowed to cure as recommended by the manufacturer.
- (2) Pipeline shall be flushed and cleaned.
- (3) All concrete anchors and thrust blocks shall be in place and allowed to cure for a minimum of three (3) days.
- (4) Earth backfill shall be sufficient to anchor the conduit against movement during the pressure testing and shall be compacted as specified in Section 14 of this specification or as shown on the drawings.
- (5) The conduit shall be braced and/or anchored at each end to restrict all potential pipe movement.
- (6) The ends of the conduit shall be plugged. The upstream plug shall have a standpipe installed vertically having a minimum diameter of two (2) inches and shall be equipped with a shutoff valve. All high points in the line shall be vented to evacuate air pockets. The conduit and the standpipe shall be slowly filled with water such that no air is entrapped during the filling operation. After filling is complete, all vents shall be closed.

b. During pressure testing, the water level in the standpipe shall be continuously maintained at a minimum of ten (10) feet above the highest invert elevation of the conduit for a period of not less than two (2) hours, unless otherwise specified in Section 14 of this specification or as shown on the drawings.

The volume of water leakage in the two (2) hour test period shall be recorded. The maximum allowable leakage (L) in gallons per hour shall not exceed 0.02 times the nominal pipe diameter (D) in inches for each 1000 feet of pipe line which is approximately 50 pipe joints ($L = 0.02 \times D$).

c. When observed leakage exceeds the allowable, leaks shall be sealed by replacement of pipe and fittings as necessary. The conduit shall be re-tested as described above. This procedure shall be repeated until the conduit leakage does not exceed the allowable specified above.

The Contractor shall be fully responsible for any and all work required to correct leakage exceeding the amount specified.

Method 3 The conduit shall be tested for leaks in the following manner:

a. Prior to pressure testing:

- (1) Joints of the assembled pipeline shall be allowed to cure as recommended by the manufacturer.
 - (2) Pipeline shall be flushed and cleaned.
 - (3) All concrete anchor and thrust blocks shall be in place and allowed to cure for a minimum of three (3) days.
 - (4) Earth backfill shall be sufficient to anchor the conduit against movement during the pressure testing and compacted as specified in Section 14 of this specification or as shown on the drawings.
 - (5) The conduit shall be braced and/or anchored at each end to prevent all potential pipe movement.
 - (6) The ends of the conduit shall be plugged and a pressure gauge shall be attached to the upstream and downstream ends. All high points along the pipeline shall be vented to permit the complete removal of all air within the pipeline. The conduit shall be slowly filled with water such that no air is entrapped during the filling operations.
- b. The testing pressure specified in Section 14 of this specification shall be continuously maintained at the upstream gauge for a minimum period of two (2) hours. The pressure at the downstream gauge shall not exceed the pressure rating of the pipe.
- c. The volume of water leakage for the two (2) hour test period shall be recorded. Maximum allowable leakage shall be in accordance with the following:

**ALLOWABLE LEAKAGE FOR PLASTIC PIPE
(GALLONS PER HOUR PER 1,000 FEET OR 50 PIPE JOINTS) ****

Nominal Pipe Size (Inches)	Test Pressure in the Pipeline – P. S. I.			
	50	100	150	200
		<u>Allowable Leakage</u>		
4	0.19	0.27	0.33	0.38
6	0.29	0.41	0.50	0.57
8	0.38	0.54	0.66	0.76
10	0.48	0.68	0.83	0.96
12	0.57	0.81	0.99	1.15
14	0.67	0.95	1.16	1.34
15	0.72	1.02	1.25	1.44
16	0.76	1.07	1.32	1.52
18	0.86	1.22	1.49	1.72

** Computation Basis

$$L = \frac{ND\sqrt{P}}{7,400}$$

Where: L = allowable leakage in gallons per hour
N = number of joints (pipe and fittings)
D = nominal diameter of pipe in inches
P = test pressure in pounds per square inch (psi)

- d. When observed leakage exceeds the allowable, leaks shall be sealed by replacement of pipe and fittings as necessary. The conduit shall be re-tested as described above.

The Contractor shall be fully responsible for any and all work required to correct leakage exceeding the amount specified.

13. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established in the contract, the quantity of each kind, size, and class of pipe will be determined to the nearest foot by measurement of the laid length along the crown centerline of the conduit. Payment for each kind, size, and class of pipe will be made at the contract unit price for that kind, size, and class. Such payment will constitute full compensation for furnishing, transporting, and installing the pipe including excavation, shoring, backfill, bedding, thrust blocks, and all fittings, appurtenances, and all other items necessary and incidental to the completion of the work. Payment for appurtenances listed separately in the bid schedule will be made at the contract prices for those items.

Method 2 For items of work for which specific unit prices are established in the contract, the quantity of each kind, size, and class of pipe will be determined as the sum of the nominal laying lengths of the sections used. Payment for each kind, size, and class of pipe will be made at the contract unit price for the kind, size, and class. Such payment will constitute for compensation for furnishing, transporting, and installing the pipe including excavation, shoring, backfill, bedding, thrust blocks, and all fittings, appurtenances, and other items necessary and incidental to the completion of the work. Payment for appurtenances listed separately in the bid schedule will be made at the contact prices for those items.

Method 3 For items of work for which specific unit prices are established in the contract, the quantity of each kind, size, and class of pipe will be determined to the nearest foot by measurement of the laid length along the crown centerline of the conduit. Payment for each kind, size, and class of pipe will be made at the contract unit price for the kind, size, and class. Such payment will constitute full compensation for furnishing, transporting, and installing the pipe including shoring, all fittings, thrust blocks, appurtenances, and other items necessary and incidental to the completion of the work. Payment for appurtenances listed separately in the bid schedule will be made at the contract prices for those items.

Methods 3 and 4 Excavation, backfill, and bedding will be paid separately under their respective bid items.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any items of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and items to which they are made subsidiary are identified in Section 14 of this specification.

TILE DRAINS

1. **APPLICABILITY**

Construction Specification 46 is applicable to the installation of clay and concrete drain tile for land drainage.

2. **MATERIAL SPECIFICATIONS**

The following material specifications are complementary to Construction Specification 46:

- a. **Clay Pipe and Drain Tile:** Specification [544](#)
- b. **Non-Reinforced Concrete Pipe:** Specification [543](#)

3. **ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS**

- a. Line and grade for tile/pipe. Include statement in items of work that pipe shall be installed so that there is no reversal of grade between joints unless specifically shown otherwise on the drawings.
- b. Kind, size and class of tile and/or pipe.
- c. Typical cross-sections, including typical bedding details.
- d. Special fittings, appurtenances, etc.
- e. Maximum and minimum trench widths.
- f. Procedures to use where unstable soils are encountered. Consider Contractor's responsibility for construction safety.
- g. Typical pipe outlets.
- h. Details of appurtenances.
- i. Location and details of any special tile/pipe bedding requirements.
- j. Use or restrictions of automatic backfillers.
- k. Location of required compacted backfill.
- l. Details of any special fittings.
- m. Type of joint required (including spacers where required).
- n. Type, kind and size of materials to be used to cover joint or pipe.
- o. Type of envelope or filter.

- p. Gradation of sand-gravel envelope or filter material. Note the limits of the moisture content of sand material so bulking will be avoided.
- q. Directions for covering pipe with envelope or filter material. Provide caution to avoid the dropping of gravel/rock materials directly on clay tile.

4. DISCUSSION OF METHODS

Methods are included in Section 4, 5, and 7. The methods are self-explanatory.

CONSTRUCTION SPECIFICATION

46. TILE DRAINS

1. SCOPE

The work shall consist of furnishing and installing drain tile and necessary fittings and appurtenances.

2. MATERIALS

Unless otherwise specified, the drain tile and fittings shall conform to the requirements of Material Specification 543 or Material Specification 544, whichever is applicable.

3. EXCAVATION

Unless otherwise specified, excavation for the installation of each tile line shall begin at the outlet end and progress upstream.

The trench or excavation for the tile shall be constructed to the depths and cross-sections shown on the drawings. The trench width may be increased above the top of the tile, at the option of the Contractor.

Trench shields, shoring and bracing, or other methods necessary to safeguard construction personnel and to prevent damage to the existing improvements shall be furnished, placed, and subsequently removed by the Contractor.

4. PREPARING THE TILE BED

Method 1 In stable soils the tile shall be firmly and uniformly bedded throughout its entire length to the specified depth and in the specified manner.

When the bottom of the trench does not provide a sufficiently stable or firm foundation for the drain tile, cradles for the tile (constructed of timber or fabricated lumber of a cleat-and-rail type construction), a sand-gravel mix or other approved materials shall be used to stabilize the bottom of the trench.

Drain tile shall not be laid on a rock foundation. In the event that boulders, rocks or ledge rock or cemented materials that prevent satisfactory bedding are encountered at the required grade with the trench cross-section, the trench shall be excavated to a minimum depth of six (6) inches below grade and backfilled to grade with a sand-gravel mixture or other approved material. The bedding material shall be shaped to grade and compacted.

Method 2 Tile shall be bedded as shown on the drawings or as specified in Section 10 of this specification.

5. LAYING TILE AND JOINT COVERING

Method 1 Gaps between tile ordinarily shall be from one-eighth (1/8) inch to one-quarter (1/4) inch in clay, clay loam and cohesive soils; and without gaps in sandy soils and on lines to convey water with no intention of providing drainage.

Where tile is installed with the width of joint opening exceeding the limits stated above for non-cohesive silts, and fine and medium sands, the joint shall be covered with a permanent type material such as coal tar pitch treated roofing paper, fiber glass sheet or mat, or plastic sheeting.

For tile installations on a curve alignment, the outside tile gap shall be covered with tile bats (broken tile) or covered as described above when the gap exceeds the recommended gap for the type of soil encountered. To maintain the gap within the allowable range, the inside pipe lip may be chipped and fitted to secure the required joint opening.

The ends and inside surfaces of all tile shall be kept clean during installation. All earth or other extraneous material within the tile shall be removed before installation of the next tile section. At the end of each day's work and when laying has been temporarily suspended, the inlet end shall be blocked so that earth or other extraneous materials will not enter the tile. The upper end of each tile line shall be blocked with permanent type materials following satisfactory completion of tile installation.

Method 2 Tile shall be laid and joints shall be covered in the manner shown on the drawings or as specified in Section 10 of this specification.

6. CONNECTIONS

Lateral connections will be made with manufactured junctions comparable in strength with the specified tile unless otherwise specified.

Where existing tile lines not shown on the drawings are crossed, they shall be bridged across the new trench or they shall be connected into the new tile lines, as directed by the Engineer.

7. BLINDING OR FILTER MATERIAL

Method 1 As soon as the tiles are placed satisfactorily, they shall be blinded by covering with friable soil materials to a minimum depth of six (6) inches. Material used for blinding shall not be frozen and, unless otherwise specified in Section 10 of this specification, shall contain no rocks or stones that when dropped may cause tile damage. Sandy and other non-cohesive soils shall not be used for blinding unless the joints are covered. All tile placed during any day shall be blinded at the completion of the day's work activities.

Method 2 Tile shall be covered with sand and gravel meeting the gradation, quality, quantities, and dimensions and installed as shown on the drawings or as specified in Section 10 of this specification. Material used for blinding shall not be frozen or contain rocks or stones that when dropped may cause tile damage. All tile placed during any day shall be blinded at the completion of the day's work activities.

Method 3 Unless otherwise specified, tile shall be covered with material obtained from required trench excavations.

8. BACKFILLING

The backfilling of the trench shall be completed as rapidly as consistent with the soil conditions.

Automatic backfilling machines may be used only when approved by the Engineer. Backfill shall extend above the ground surface, be well rounded and centered over the trench.

Unless otherwise specified, where drain tile are installed under roads and at other designated locations shown on the drawings, the backfill shall be placed in successive layers of not more than six (6) inches and each layer shall be compacted before the next layer is placed. The density of the compacted backfill shall not be less than the density of the surrounding adjacent earth materials unless otherwise specified in Section 10 of this specification.

9. MEASUREMENT AND PAYMENT

For items of work for which specific unit prices are established in the contract, the quantity of each kind, size and class of tile will be determined to the nearest foot of length measured along the centerline of the installed tile. Payment for each kind, size and class of tile will be made at the contract unit price for that kind, size and class of tile. Such payment will constitute full compensation for furnishing, transporting and installing the tile, including excavation, shoring, backfill and all fittings, appurtenances and other items necessary and incidental to the completion of the work. Payment for appurtenances listed separately in the bid schedule will be made at the contract prices for the sizes and types of appurtenances listed.

Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 10 of this specification.

CORRUGATED METAL PIPE

1. APPLICABILITY

Construction Specification 51 is applicable to the installation of all types of corrugated metal pipe conduits.

2. MATERIAL SPECIFICATIONS

The following specifications are complementary to Construction Specification 51:

- a. [Coated Corrugated Steel Pipe](#). Specification 551
- b. [Aluminum Corrugated Pipe](#). Specification 552

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Line and grade of the conduit.
- b. Details of the pipe bedding including description and grading limits of the bedding material.
- c. Details of wall fittings, joint and other special pipe fittings.
- d. Details of struts or ties, as necessary.
- e. Pay limits or actual limits for excavation and backfill, if required. Due consideration of OSHA safety requirements for trench excavation should be considered for pay quantities.
- f. Applicable material specifications.
- g. Type, class, size, gauge, and length of pipe.
- h. Type of coupling and gasket, if required. Coupling bands may be detailed on the drawings and described in Section 11, or may be specified in Section 11 by describing the performance requirements by reference to ASTM A 798, Paragraph 8, Pipe Installation. Using ASTM A 798, joint watertightness may be specified per paragraph 8.2.4.6 Watertightness, however, the method of testing and the basis for determining acceptance is needed.
- i. Close riveting or double riveting, if required.
- j. Type of pipe coating, if required.
- k. Methods of measurement and payment if the contract specification includes more than one method.

- I. Backfill requirements. Compaction requirements should be equal to requirements for the adjacent embankment for principal spillways or similar installations.

4. DISCUSSION OF METHODS

a. Section 10, Measurement and Payment

The methods are self-explanatory.

When specifications are prepared using electronic procedures and all but one method is deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

51. CORRUGATED METAL PIPE

1. SCOPE

The work shall consist of furnishing and placing circular, arched or elliptical corrugated metal pipe and the necessary fittings.

2. MATERIALS

Pipe and fittings shall conform to the requirements of Material Specification 551 or Material Specification 552, whichever is specified.

Unless otherwise specified in Section 11 of this specification, perforated pipe furnished shall conform to the requirements for Class I perforations as described in ASTM A 760 or A 762.

3. COUPLING BANDS AND HARDWARE

Pipe joint coupling bands shall be provided meeting the requirements specified in Section 11 of this specification.

Hardware consisting of coupling bands and band fastening devices such as connecting bolts, rods, lugs and angles used in conjunction with zinc-coated iron or steel pipe shall be galvanized by the hot-dip method. Hardware used in conjunction with aluminum pipe and aluminum or aluminum-zinc alloy-coated iron and steel pipe shall be of the same material as the pipe except that hot-dip galvanized or cadmium-plated fasteners may be used. The surface of all band fastening devices for pipe specified with bituminous or polymer coating shall be coated with asphalt-mastic materials meeting the requirements of ASTM A 849. The coupling band shall be coated similar to that specified for the pipe unless otherwise specified in Section 11 of this specification.

Coupling bands shall be installed to provide straight alignment of the connecting pipe ends. Unless otherwise specified in Section 11 of this specification, the band width shall be as specified in ASTM A 760 and A 762. The bands shall be positioned to overlap adjacent pipe ends equally. The coupling bands shall be corrugated to match the corrugations of the pipe section ends being connected.

4. FABRICATION

Fabrication of appurtenant sections shall be performed as shown on the drawings and described in Section 11 of this specification. The items may consist of inlet sections, outlet sections, end sections, elbows, skew or beveled sections, rod reinforced ends, cut-off collars, or headwalls. Fabrication of these appurtenant sections shall be made from metallic-coated materials identical to those from which the attached pipe is fabricated. Fabrication shall be of a quality and finished workmanship equal to that required for the pipe.

5. HANDLING THE PIPE

The Contractor shall furnish equipment as necessary to install the pipe without damaging the pipe or coating. The pipe shall be transported and handled in a manner to prevent damage to the pipe and coating.

6. LAYING AND BEDDING THE PIPE

Unless otherwise specified, the pipe shall be installed in accordance with the manufacturer's recommendations. Pipe shall be installed so no reversal of grade between joints results unless otherwise shown on the drawings. The pipe shall be installed with the outside laps of circumferential joints pointing upstream and with longitudinal laps at the sides near the vertical midheight of the pipe.

Field welding of corrugated galvanized iron or steel pipe will not be permitted. The pipe sections shall be joined with fabricator-supplied coupling bands meeting the specified joint requirements. The coupling shall be installed as recommended by the fabricator.

The pipe shall be firmly and uniformly bedded throughout its full length to the depth and in the manner specified on the drawings.

Perforated pipe shall be installed with the perforations down and oriented symmetrically about a vertical centerline. Perforations shall be clear of any obstructions at the time the pipe is installed in its final position.

The pipe shall be loaded sufficiently during backfilling to prevent displacement from line and grade, and to maintain full contact with the bedding during the placement operations.

7. STRUTTING

When required, struts or horizontal ties shall be installed in the manner specified on the drawings. Struts and ties shall remain in position until the backfill has been placed above the top of the pipe to a height of five (5) feet or the pipe diameter, whichever is greater, or to the surface of the completed earth backfill when the fill height is less than five (5) feet above the top of the pipe. The Contractor shall remove the struts or ties following completion of the earth backfill requirements that apply.

8. EMBEDMENT IN CONCRETE

Special treatment shall be provided to pipe surfaces when embedded or attached to concrete and the pipe material is aluminum or aluminum-coated and aluminum-zinc alloy coated. Potential contact surfaces in contact with concrete and masonry surfaces shall be coated with two (2) coats of a bituminous paint of the cut-back type. Placement of the pipe shall be such that direct metal-to-metal contact with

other metallic materials, such as embedded steel reinforcement or water control gates, is prevented.

9. REPAIR OF DAMAGED COATING

Any damage to the metallic coating shall be repaired by cleaning the damaged surface area by sand blasting, power disk sanding or wire brushing. All loose and cracked coating, dirt, and any products of corrosion shall be removed prior to application of paint. Oil and grease materials shall be removed by use of a solvent. The surface shall be clean and dry during the painting period and until the coating has completely dried.

Painting shall be accomplished by one of the following options based upon installed exposure conditions of the pipe as determined by the Engineer.

Normal exterior or interior atmospheric exposure:

- a. Zinc dust - zinc oxide primer, ASTM D 79 and D 520
- b. Singles package, moisture cured urethane prime in silver metallic color, or
- c. Zinc-rich cold galvanized compound, brush, or aerosol application.

Submergence in water exposure:

- a. Zinc dust-zinc oxide primer, ASTM D 79 and D 520
- b. Zinc dust paint, ASTM D 4146

When the metallic coating is damaged in any individual area larger than twelve (12) square inches, or if more than 0.2 percent of the total surface area of a single pipe section is damaged, that section of pipe will be rejected.

Breaks or scuffs in bituminous coatings that are less than 36-square inches in area shall be repaired by the application of two coats of hot-asphaltic paint or a coating of cold-applied bituminous mastic. The repair coating shall be a minimum of 0.05-inches thick after hardening and shall bond securely and permanently to the pipe and coating. The material shall meet the minimum physical requirements for bituminous coating contained in ASTM A 849 and A 885. Whenever individual breaks exceed 36-square inches in area or when the total area of breaks exceeds 0.5 percent of the total surface area of an individual pipe section, that section of pipe will be rejected.

Bituminous coating damaged by welding of coated pipe or pipe fittings shall be repaired as specified in this Section for breaks or scuffs in bituminous coatings.

Breaks or scuffs in polymer coatings that are less than 36-square inches in area shall be repaired by the application of a polymer material similar to and compatible

with the durability, adhesion and appearance of the original polymer coating, as described in ASTM A 849, paragraph 6.8. The repair coating shall be a minimum thickness of 0.010-inches (10 mils) after drying. Whenever individual breaks exceed 36-square inches in area or when the total area of breaks exceed 0.5 percent of the total surface area of the individual pipe section, that section of pipe will be rejected.

10. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established in the contract, the quantity of each type, class, size and gauge of pipe will be determined to the nearest 0.1 foot by measurement of the laid length of the pipe along the centerline of the pipe. Payment for each type, class, size and gauge of pipe will be made at the contract unit price for that type, class, size and gauge of pipe. Such payment will constitute full compensation for furnishing, transporting and installing the pipe and fittings and all other items necessary and incidental to the completion of the work, except items designated as "special fittings". Special fittings are those sections of pipe requiring special fabrication to meet layout requirements. Payment for special fittings will be made at the contract unit price for special fittings (CMP).

Method 2 For items of work for which specific unit prices are established in the contract, the quantity of each type, class, size and gauge of pipe will be determined as the sum of the nominal laying lengths of the pipe sections installed. Payment for each type, class, size and gauge of pipe will be made at the contract unit price for that type, class, size and gauge of pipe. Such payment will constitute full compensation for furnishing, transporting and installing the pipe and fittings and all other items necessary and incidental to the completion of the work except items designated as "special fittings". Special fittings are those sections of pipe requiring special fabrication to meet layout requirements. Payment for special fittings will be made at the contract unit price for special fittings (CMP).

Method 3 For items of work for which specific lump sum prices are established in the contract, payment for corrugated metal pipe structures will be made at the contract lump sum price. Such payment will constitute full compensation for furnishing, fabricating, transporting, and installing the pipe structure complete with metal pipe, fittings, and appurtenances, and all other items necessary and incidental to completion of the work which includes, except as otherwise specified, required excavation, dewatering, and earth backfill.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and items to which they are made subsidiary are identified in Section 11 of this specification.

INSTRUCTIONS FOR USE OF CONSTRUCTION SPECIFICATION 52

STEEL PIPE

1. APPLICABILITY

Construction Specification 52 is applicable to the installation of steel pipe conduits.

2. MATERIAL SPECIFICATIONS

Material Specifications [554](#) and [581](#) are complementary to Construction Specification 52.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Details of the bedding, including description and grading limits of the bedding material.
- b. Excavation requirements. If Measurement and Payment Method 1 or 2 is used, a bid item and items of work and construction details for excavation and backfill would normally be covered under Construction Specification [21](#) and [23](#). If Measurement and Payment Method 3 or 4 is used, construction details for excavation can either be covered in Section 12, or as a subsidiary item under Construction Specification [21](#).
- c. Method of backfill selected from Section 10.
- d. Pay limits or actual limits for excavation and backfill, if required.
- e. Kind of pipe. Include name, type, grade, finish, weight class, and wall thickness as required. (See appropriate reference specifications.)
- f. Size of pipe.
- g. Length of pipe.
- h. Type of protective lining and coating if required (Refer to AWWA Standard C203, AWWA Standard C209, or AWWA Standard C214 for detailed information).

Note: In accordance with AWWA C203, field welded pipe 27-inch diameter and larger is large enough to allow entry of personnel to clean the welded surface and apply primer and enamel. Therefore, lined pipe smaller than 27-inch diameter should not be field welded.

- i. Type of joint and details of special joints.
- j. Details of wall fittings and other special fittings and appurtenances.
- k. Watertightness or pressure test requirements, if applicable.
- l. Shop coating of fittings if the vinyl option is specified as discussed in Section 6.

- m. Bonding details for cathodic protection, if applicable.
- n. Method of field lining, coating, wrapping, and repair selected from Section 7.
- o. Method of measurement and payment in Section 11.

4. DISCUSSION OF METHODS

a. Section 7, Field Lining, Coating, Wrapping, and Repair

- (1) Method 1 is intended for use when hot-applied linings and/or coatings are required, or for repairing hot applied linings and/or coatings.
- (2) Method 2 is intended for use when cold-applied tapes are required for wrapping assembled joints and for repair of hot applied coatings.
- (3) Method 3 is intended for use when the pipe is coated in accordance with AWWA Standard C214.

b. Section 10, Backfill

The methods are self-explanatory.

c. Section 11, Measurement and Payment

The methods are self-explanatory.

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

52. STEEL PIPE

1. SCOPE

The work shall consist of furnishing and installing steel pipe complete with lining, coating, fittings, and appurtenances.

2. MATERIALS

[Steel pipe and fittings](#) shall conform to the requirements of Material Specification [554](#).

Unless otherwise specified, special fittings and appurtenances shall be of the same material as the pipe.

[Welding electrodes](#) shall conform to the requirements of Material Specification [581](#).

Coating and lining materials shall conform to the requirements of the following:

- a. AWWA C203, Standard for Coal-Tar Protective Coatings and Linings for Steel Water Pipelines, Enamel and Tape - Hot-Applied;
- b. AWWA C209, Standard for Cold-Applied Tape Coatings for the Exterior of Special Sections, Connections, and Fittings for Steel Water Pipelines;
- c. AWWA C214, Standard for Tape Coating Systems for the Exterior of Steel Water Pipelines;

and as specified below:

Shop coating materials shall conform to the requirements of AWWA Standard C203 and AWWA Standard C214 and as specified in Section 12 of this specification.

Shop lining materials shall conform to the requirements of AWWA Standard C203.

Field coating and coating repair materials shall conform to the requirements of AWWA Standard C203, AWWA Standard C209, AWWA Standard C214 and, as specified in Section 12 of this specification.

Field lining materials shall conform to the requirements of AWWA Standard C203 and as specified in Section 12 of this specification.

3. COATING AND LINING

Shop coating of pipe, specials, and fittings shall be in accordance with either AWWA Standard C203, AWWA Standard C209, or AWWA Standard C214 and as specified in Section 12 of this specification.

Shop lining of pipe, specials, and fittings shall conform to the requirements of AWWA Standard C203.

4. EXCAVATION

Excavation shall be in accordance with Construction Specification 21 or as specified in Section 12 of this specification.

5. LAYING AND BEDDING THE PIPE

Pipe shall be installed to the line and grade shown on the drawings. Unless otherwise specified, the pipe shall be installed so that there are no reversals of grade between joints, and shall also be installed in accordance with the manufacturer's recommendations. The pipe shall be firmly and uniformly bedded to the depth and in the manner specified on the drawings. An ample "bell hole" working area may be left at pipe joints to perform welding, coating, etc., activities. The "bell hole" area shall then be bedded, as specified, prior to backfill operations.

The pipe shall be weighed down sufficiently to prevent its displacement from the bedding during placement of the backfill under the haunches.

6. JOINTS AND CONNECTIONS

Pipe joints shall conform to the details shown on the drawings and shall be sound and watertight at the pressures specified in Section 12 of this specification.

Welded Joints. Welding and welded joints shall conform to the welding procedure details and requirements of AWWA Standard C206. Field welding shall be done in such a way as to avoid burning the protective coating on the pipe except in the immediate vicinity of the weld.

Where welded field joints are used, they shall be single welded butt joints or lap welded slip joints, as shown on the drawings. Special closure lap joints shall be used as described in AWWA Standard C206.

Bell and Spigot Joints. The dimensions of bells and spigots shall be in accordance with the manufacturer's standard design dimensions and tolerances.

The pipe shall be laid with the bell oriented upstream. The spigot end shall be seated in the bell to a depth as recommended by the manufacturer. The spigot, when seated, shall compress the gasket radially in its annular recess to provide a positive seal. Joints with fishmouthed gaskets will be taken apart and re-seated with a new gasket.

Rubber gaskets shall meet the requirements of AWWA Standard C200.

Mechanical Couplings. The ends of pipe to be connected with mechanical couplings shall be machined so as to allow coupling the pipe sections without damaging or displacing the gaskets and to insure uniform end separation of the pipes. Machined ends of the pipe that receive the coupling sleeves shall be free from dents, gouges, rust, or scale. The pipe and couplings shall be assembled with continuous rubber

ring gaskets conforming to the dimensions and tolerances recommended by the pipe manufacturer. Coupling followers shall be drawn up evenly to insure uniform pressure on the gaskets.

Grooved and shouldered joints shall be furnished and installed in accordance with AWWA Standard C606.

Flanged Joints. All steel ring flanges shall be fabricated in accordance with AWWA Standard C207. Gaskets shall be either a neoprene cloth-insert 1/16-inch or 1/8-inch thick or red rubber 1/16-inch thick. The gasket shall be full face where used between flat face flange surfaces. All flanged joints shall be made up tightly and shall not leak.

Fitting and Coupling Coatings. Compression couplings, mechanical couplings, and flanged fittings shall be shop coated with the AWWA Standard C203 coal tar enamel coating, as recommended by the coating manufacturer, or a factory-applied vinyl coating at least 12 mils thick and as specified in Section 12 of this specification. All bolts furnished for flanges, couplings, and other types of bolted connections shall be stainless steel or low alloy steel and shall be field coated with a coal tar enamel or vinyl coating after installation.

7. FIELD LINING, COATING, WRAPPING, AND REPAIR

Lining and coating or wrapping of field joints or connections and repair of damage to the wrap or coating on pipe, couplings, fittings, and appurtenances shall be made in accordance with Section 12 of this specification and one of the following methods:

Method 1 All field coating, lining, and repair shall be as specified in AWWA Standard C203;

Method 2 All field wrapping and repair shall be as specified in AWWA Standard C209 with Type I or II tape;

Method 3 All field wrapping and repair shall be as specified in AWWA Standard C214;

All Methods The following provisions apply to all methods of field coating, wrapping, and coating repair.

Surface Preparation. Bare steel surfaces shall be prepared for coating by removing all grease and oil or other soluble contaminants with solvent commercial cleaners (wiping, dipping, or steam) or vapor degreasing. After degreasing, surfaces shall be cleaned with hand tools to remove all loose scale rust and other loose detrimental foreign matter.

On previously coated surfaces, all dirt, paper and other foreign matter, and loose coating shall be removed. Kraft paper, whitewash, or other surface protective layers shall be removed at least 12 inches on either side of the bare steel to be coated.

Welds shall be cleaned of all welding slag, splatter, and scale. Sharp edges or burrs that could puncture or cut the coating shall be removed by grinding or filing. All welds shall be allowed to cool before applying primer or coatings.

Primer Application. After surface preparation is complete, primer shall be thoroughly mixed and applied in strict adherence to manufacturer's instructions. The primer shall be permitted to dry to the consistency recommended by the manufacturer prior to applying the coating. No foreign matter shall come in contact with the primed surface prior to application of the coating. Application of primer to surfaces shall be limited to that amount of area that can be wrapped during the same work-shift. Primed areas not wrapped during the same work-shift shall be re-primed. Cold weather applications of primer shall be done in accordance with AWWA Standard C203.

Coating Application. The specified coating shall be applied in accordance with the manufacturer's recommendations, unless otherwise specified.

After assembly, all pipe joints shall be field wrapped in accordance with AWWA C209 or AWWA C214, as appropriate. Surface preparation and primer application to the ends of the pipe to be wrapped shall be as previously described in this specification. A tape or filler tape shall be cigarette wrapped over the annular ring of the joint. The pipe coating shall be primed two (2) inches back from the coating cutback and two (2) layers of tape shall be wrapped overlapping two (2) inches of pipe coating on one side of the joint, extending across the joint and overlapping two (2) inches of coating on the other side of the joint. Coal tar enamel coating cutback edges shall be tapered back until one (1) inch of coal tar is exposed on the taper prior to priming and wrapping. Wraps shall be terminated on the underside of the pipe. Tape widths shall be six (6) inches for pipe greater than eight (8) inches diameter and four (4) inches for pipe two (2) to eight (8) inches in diameter.

Welded field joints, of lined pipe, shall be lined in accordance with AWWA Standard C203, Section 4.3, or as specified in Section 12 of this specification.

Repair and Patching Factory Coatings. All loose or disbanded material shall be removed from the area of the "holiday". All points, burrs, or rough edges shall be smoothed to a feathered edge. The surface shall be cleaned and prepared as specified for joints, couplings, and fittings. The area to be cleaned and prepared shall be at least twice the size of the "holiday". The repair coating shall be worked onto the surface of the steel so as to leave no voids or wrinkles on the surface.

Coal tar enamel coatings shall be repaired in accordance with AWWA Standard C203, Section 2.15. Tape coatings shall be repaired in accordance with AWWA Standard C214, Section 3.4, Coating Repair. The repair shall be made by wrapping tape around the circumference of the pipe.

All damaged vinyl coat areas shall be cleaned and recoated in accordance with the manufacturer's recommendation.

8. HANDLING THE PIPE

The Contractor shall furnish such equipment as is necessary to place the pipe without damaging the pipe or coating. Coated pipe shall be handled in the manner specified in AWWA Standard C203 or C214, as appropriate.

9. PRESSURE TESTING

If pressure testing of the conduit is specified, it shall be performed as follows:

- a. Placement of backfill before pressure testing shall be as specified in Section 10 of this specification.
- b. Before pressure testing, the pipeline shall be flushed and cleaned.
- c. The pipeline shall not be pressure tested until concrete in the anchor and thrust blocks has attained the minimum specified compressive strength.
- d. The total conduit, or section of the conduit, to be tested shall be filled with clean water at the rate specified and tested at the pressure specified in Section 12 of this specification.
- e. The section of conduit being tested shall be allowed to stand full of water for a minimum of 24 hours before the start of pressure and leakage test. Test pressure shall be held constant for 2 hours. If the amount of water loss exceeds the limit specified, the leaks shall be repaired and the conduit shall be re-tested. The procedure shall be repeated until the amount of water loss is within the limits specified in Section 12 of this specification.

10. BACKFILL

Method 1 Backfill, in accordance with Construction Specification 23 and Section 12 of this specification, shall be made only in sufficient amount to hold the conduit in place during testing, with the following exceptions:

- a. Compacted backfill shall be placed to its final depth as shown on the drawings at vertical and horizontal angle points, road crossings, and thrust blocks. Backfill shall be placed in such a way that the conduit and joints will not be subject to displacement or damage.
- b. All joints and connections shall be completely exposed for visual inspection during testing, except at locations that maybe exempt as outlined in 10.a.

Method 2 Backfill, in accordance with Construction Specification 23 and Section 12 of this specification, shall be to its final depth as shown on the drawings for the section of conduit being tested.

Use with Either Method The Contractor shall be fully responsible for any and all work required to repair any leakage when water loss exceeds the amount specified in Section 12 of this specification. After pressure testing is satisfactorily completed, the backfill shall be placed in accordance with Construction Specification 23 and Section 12 of this specification.

11. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established in the contract, the quantity of each type and size of pipe will be determined to the nearest 0.1 foot by measurement of the installed length of pipe along the centerline of the pipe. Payment for each type and size of pipe will be made at the contract unit price for that type and size of pipe. Such payment will constitute full compensation for furnishing, transporting, and installing the pipe, including the necessary fittings and all other items necessary and incidental to the completion of the work.

Method 2 For items of work for which specific unit prices are established in the contract, the quantity of each type and size of pipe will be determined to the nearest 0.1 foot by measurement of the installed length of pipe along the centerline of the pipe. Payment for each type and size of pipe will be made at the contract unit price for that type and size of pipe. Such payment will constitute full compensation for furnishing, transporting, and installing the pipe, complete in place, including the necessary fittings and all other items necessary and incidental to the completion of the work except the special fittings and appurtenances listed separately in the bid schedule. Payment for each special fitting and appurtenance will be made at the contract unit price for that type and size of fitting or appurtenance.

Method 3 For items of work for which specific unit prices are established in the contract, the quantity of each type and size of pipe will be determined to the nearest 0.1 foot by measurement of the installed length of pipe along the centerline of the pipe. Payment for each type and size of pipe will be made at the contract unit price for that type and size of pipe. Such payment will constitute full compensation for furnishing, transporting, and installing the pipe, including excavation, shoring, backfill, and all the necessary fittings and all other items necessary and incidental to the completion of the work.

Method 4 For items of work for which specific unit prices are established in the contract, the quantity of each type and size of pipe will be determined to the nearest 0.1 foot by measurement of the installed length of pipe along the centerline of the pipe. Payment for each type and size of pipe will be made at the contract unit price for that type and size of pipe. Such payment will constitute full compensation for furnishing, transporting, and installing the pipe, complete in place, including excavation, shoring, backfill, and all the necessary fittings and all other items necessary and incidental to the completion of the work except the special fittings and appurtenances listed separately in the bid schedule. Payment for each special fitting and appurtenance will be made at the contract unit price for that type and size of fitting or appurtenance.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract, but not listed in the bid schedule, will be included in the payment for the item of work to which it is made subsidiary. Such items, and the items to which they are made subsidiary, are identified in Section 12 of this specification.

DUCTILE-IRON PIPE

1. APPLICABILITY

Construction Specification 53 is applicable to the installation of ductile-iron pipe and fittings used in water distribution systems.

2. MATERIAL SPECIFICATIONS

Material Specification [553](#) is complementary to Construction Specification 53.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Line and grade of the conduit. Include a statement in items of work that the pipe shall be installed so reversal of grade between joints does not occur unless shown on the drawings.
- b. Details of bedding, including description and grading limits of bedding material.
- c. Method of backfill consistent with minimum job requirements, complexity, and inspection compliance considerations. Refer to Construction Specification [23](#), [Earthfill](#), if used.
- d. Pay limits or actual limits for excavation, minimum trench width, and any special considerations necessary. Consider the need for Contractor's compliance with the excavation safety requirements of OSHA.
- e. Pay limits or actual limits of backfill, compaction requirements or other special methods of performance and controlling backfill, as appropriate. (AWWA, Standard C600 provides a prepared standard that may be referenced for installation, as appropriate.) Provide the necessary guidance when sand bedding is specified so bulking potential is avoided.
- f. Kind of pipe (thickness class and rated working pressure).
- g. Size of pipe (diameter).
- h. Laying length of pipe.
- i. Type of joints for pipe and fittings (mechanical push-on or flanged). Pipe joining details if different than manufacturer's recommendations.
- j. Lining thickness and coating for pipe (interior and exterior) and methods of repair. Loose polyethylene pipe encasement, tube or sheet form, for corrosion protection can be specified as per ANSI A21.5 (AWWA C105). Provide placing and handling details as appropriate. Protective coatings applied to the pipe during manufacture must be specified on the job basis. Outline minimum repair procedures to correct tears and rips in the loose encasement coverings.

- k. Pressure and leakage test requirements including the duration of the test period.
- l. Details of special fittings and appurtenances.
- m. Concrete thrust and anchor block specifications and details.

4. DISCUSSION OF METHODS

a. Section 7, Backfill

Methods are self-explanatory.

b. Section 8, Measurement and Payment

When deduction in measured pipe length will be made for special fittings and other appurtenances, outline procedures in Section 9 that will be implemented to determine pipe length for payment purposes.

CONSTRUCTION SPECIFICATION

53. DUCTILE-IRON PIPE

1. SCOPE

The work shall consist of furnishing and installing ductile-iron pipe, fittings, and appurtenances as specified in Section 9 of this specification and as shown on the drawings.

2. MATERIALS

Ductile-iron pipe and fittings shall conform to the requirements of Material Specification [553, Ductile-Iron Pipe and Fittings](#). Thickness class of pipe and rated working pressure shall be as specified in Section 9 of this specification or as shown on the drawings.

Unless otherwise specified, special fittings and appurtenances shall be the same material as the pipe.

3. LAYING AND BEDDING THE PIPE

Pipe shall be installed to the lines and grades shown on the drawings with bell socket ends aligned upstream unless otherwise specified. The pipe shall be installed in accordance with the manufacturer's recommendations, unless otherwise specified. Two (2) copies of the pipe manufacturer's installation instructions shall be provided to the Engineer prior to any pipe placement. The pipe shall be firmly and uniformly bedded within the trench throughout the entire length of the pipe section to the depth and in the manner specified. Bell holes for flanged, push-on or mechanical joint pipe shall be provided as necessary to allow space for joint assembly and to permit the pipe barrel to be uniformly supported on the bedding.

4. JOINTS AND CONNECTIONS

Pipe joints shall conform to the details shown on the drawings and shall be sound and watertight at the pressures specified in Section 9 of this specification.

5. HANDLING THE PIPE

The Contractor shall furnish all equipment and facilities needed to handle, store, and place the pipe without damaging the pipe, lining, encasement or coating. Pipe coating, encasement or lining that is damaged shall be repaired by methods recommended by the manufacturer unless otherwise specified in Section 9 of this specification.

6. PRESSURE TESTING

Pressure testing of the conduit, when specified, shall be conducted as follows:

- a. Placement of backfill before pressure testing shall be as specified in Section 7 of this specification.

- b. Before pressure testing, the pipeline shall be flushed and free of all foreign material.
- c. The pipeline shall not be pressure tested until concrete for anchor and thrust blocks has attained the minimum specified compressive strength unless other specified methods of thrust restraint is provided.
- d. The total conduit or continuous section of conduit to be tested shall be filled with clean water at a rate not to exceed the maximum specified and tested at the pressures specified in Section 9 of this specification.
- e. The section of conduit being tested shall be allowed to stand full of water for a minimum of 24 hours before the start of pressure and leakage tests. Test pressures shall be held constant for two (2) hours. When the amount of water loss exceeds the maximum allowable loss specified in Section 9 of this specification, the leak(s) shall be repaired or otherwise corrected and the conduit shall be retested. The testing procedure shall be repeated until the requirements of the specifications are met.

7. BACKFILL

Method 1 Backfill in accordance with Section 9 of this specification shall be accomplished only in sufficient amount to hold the conduit in place during testing, with the following exceptions:

- a. Compacted backfill shall be placed to its final depth as shown on the drawings at vertical and horizontal deflection points, road crossings, and thrust blocks. Backfill shall be placed in a manner that conduit and joint displacement does not occur.
- b. All joints and connections shall be completely exposed for visual observation during testing, except at locations described in 10.a. above.

Method 2 Backfill in accordance with Section 9 of this specification shall be to the final depth as shown on the drawings for the section of conduit being tested.

Use with Either Method The Contractor shall be fully responsible for any and all work required to correct any leakage when the leakage test results in water loss that exceeds the amount specified in Section 9 of this specification.

8. MEASUREMENT AND PAYMENT

For items of work for which specific unit prices are established in the contract, the quantity of each size, and thickness class of pipe will be determined to the nearest foot by measurement of the installed length of pipe along the crown centerline of the conduit. Payment for each size and thickness class of pipe will be made at the contract unit price for that size and thickness class of pipe. Such payment will

constitute full compensation for furnishing, transporting, handling and installing the pipe and necessary fittings and appurtenances complete in place.

Compensation for any item of work described in the contract but not listed will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 9 of this specification.

ROCK RIPRAP

1. APPLICABILITY

Construction Specification 61 is applicable to equipment placed or hand-placed rock riprap, granular filter and granular bedding. It is also applicable for riprap placed over geotextile fabrics installed in accordance with Construction Specification 95.

2. MATERIAL SPECIFICATIONS

Material Specifications 521, 523, and 592 are complementary to Construction Specification 61. Select Rock Type 1, 2, or 3 of Specification 523, Section 2, as appropriate and specify in Section 8.

- a. Rock Type 1 - For exposure conditions that will require sound and very durable material due to aggressive environment and demanding requirements, or in locations where replacement or repair would be very difficult if breakdown or other failure were to occur.
- b. Rock Type 2 - A lesser degree of durability is required while meeting a good standard of performance. The hazard is not a major consideration and accessibility for repair or replacement is practical. No design changes are necessary for utilization of this rock type.
- c. Rock Type 3 - Does not meet our normal requirements for quality, but due to the lack of on-site availability or availability of better materials, it is advantageous to use. Design changes, such as greater rock thickness and/or flatter slopes, may be required to compensate for the lack of long-term durability. More frequent repair and replacement should be anticipated.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Complete plans and cross-sections of the required riprap.
- b. Type of placement (equipment or hand-placed).
- c. Pay limits, where applicable.
- d. Foundation preparation requirements, if any.
- e. Gradation requirements for materials.
- f. Screening, selection or other processing requirements, to insure obtaining rock of the required quality and grading. For example, if angular to sub-angular rock is preferred over sub-rounded to rounded rock, specify this requirement in Section 8.
- g. Sources of materials, if the sources are to be specified. When sources are designated in the contract, the adequacy of quantity and quality of usable

material at each source must be determined in advance by: (1) geologic investigations with adequate sampling and testing, (2) specific case history which establishes the quality by satisfactory performance under comparable conditions of use and exposure or acceptable pre-qualification by other agencies.

- h. ASTM D 5240 should be specified to check for rock resistance to freeze-thaw damage on sites with large volumes of riprap, at highly hazardous locations, or on sites that would be very difficult to repair if rock breakdown occurs. Acceptance limits in the specification must be evaluated and strengthened, if needed, to ensure the use of the appropriate rock type and quality.
- i. Method(s) of measurement and payment.
- j. When geotextile filters are specified, Construction Specification 95 should be used.

4. DISCUSSION OF METHODS

a. Section 8, Measurement and Payment

The methods listed below provide two basic options for measuring and paying for rock riprap using either weight (ton) or volume (cubic yard) methods. Advantages of each option are as follows:

Weight - Ton methods would be more appropriate for quarried rock imported to a site. Contractors usually pay their supplier for quarried rock by the ton. Payment by the ton provides for direct pricing without the need to convert from a ton basis to cubic yards. Variations in riprap characteristics such as rock specific gravity, transportation and placement losses, denseness of placement, etc., make it necessary for the contractor to add contingencies that include these variations.

Volume - Cubic yard methods would be more appropriate for riprap that is produced from on-site locations, for gathered field stone, quarried rock sold by the truck load, and other situations where a certified scale is not readily available. It would also be appropriate for small quantities of rock where quantity measurement is not complex or a major task. Cubic yard methods can also be an advantage where the riprap end section is uniform for long reaches on larger projects. The elimination of the need to keep track of delivery tickets may be a considerable time saving.

Cubic yard methods can be expected to impose some contingency considerations from the contractor due to the necessity to convert from tons to cubic yards in quantity estimation.

- (1) Methods 1, 2, and 3 provide various means of measurement and are intended for use where filter or bedding aggregate, if any, is to be paid for as a separate item.

- (2) Method 4 is intended for use where filter or bedding aggregate is a minor item and payment for it is to be included in the payment for rock riprap.
- (3) Methods 5 and 6 are intended for use when geotextile filters are specified, or when no filter, bedding aggregate, or geotextile are specified.

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

61. ROCK RIPRAP

1. SCOPE

The work shall consist of the construction of rock riprap revetments and blankets, including filter or bedding where specified.

2. MATERIALS

Rock riprap shall conform to the requirements of Material Specification 523 or, if so specified shall be obtained from designated sources. It shall be free from dirt, clay, sand, rock fines and other materials not meeting the required gradation limits.

At least thirty (30) days prior to delivery of rock from other than designated sources, the Contractor shall designate in writing the source from which rock materials will be obtained and provide information satisfactory to the Engineer that the material meets contract requirements. The Contractor shall provide the Engineer free access to the source for the purpose of obtaining samples for testing. The size and grading of the rock shall be as specified in Section 8.

Rock from approved sources shall be excavated, selected, and processed to meet the specified quality and grading requirements at the time the rock is installed.

When specified in Section 8 or, when requested by the Contracting Officer, a gradation quality control check shall be made by the Contractor and subject to inspection by the Engineer. The test shall be performed at the work site, in accordance to ASTM D 5519 Test Method B Size, *Size-Range Grading*, on a test pile of representative rock. The weight or size of the test pile shall be large enough to ensure a representative gradation of rock from the source and to provide test results within a five (5) percent accuracy.

Based on a specific gravity of 2.65 (typical of limestone and dolomite), and assuming the individual rock is shaped midway between a sphere and a cube, typical size/weight relationships are:

Sieve Size of Rock	Approximate Weight of Rock	Weight of Test Pile
16 inches	300 pounds	6000 pounds
11 inches	100 pounds	2000 pounds
6 inches	15 pounds	300 pounds

The results of the test shall be compared to the gradation required for the project. Test pile results that do not meet the construction specifications shall be cause for the rock to be rejected. The test pile that meets contract requirements shall be left on the job site as a sample for visual comparison. The test pile shall be used as part of the last rock riprap to be placed.

Filter or bedding aggregates when required, shall conform to Material Specification 521, unless otherwise specified. Geotextiles shall conform to Material Specification 592.

3. SUBGRADE PREPARATION

The subgrade surfaces on which the rock riprap, filter, bedding or geotextile is to be placed shall be cut or filled and graded to the lines and grades shown on the drawings. When fill to subgrade lines is required, it shall consist of approved materials and shall conform to the requirements of the specified class of earthfill.

Rock riprap, filter, bedding or geotextile shall not be placed until the foundation preparation is completed and the subgrade surfaces have been inspected and approved.

4. EQUIPMENT-PLACED ROCK RIPRAP

The rock riprap shall be placed by equipment on the surfaces and to the depths specified. The rock riprap shall be installed to the full course thickness in one operation and in such a manner as to avoid serious displacement of the underlying materials. The rock for riprap shall be delivered and placed in a manner that will ensure that the riprap in-place shall be reasonably homogeneous with the larger rocks uniformly distributed and firmly in contact one to another with the smaller rocks and spalls filling the voids between the larger rocks. Some hand placing may be required to provide a neat and uniform surface.

Rock riprap shall be placed in a manner to prevent damage to structures. Hand placing will be required as necessary to prevent damage to any new and existing structures.

5. HAND-PLACED ROCK RIPRAP

The rock riprap shall be placed by hand on the surfaces and to the depths specified. It shall be securely bedded with the larger rocks firmly in contact one to another without bridging. Spaces between the larger rocks shall be filled with smaller rocks and spalls. Smaller rocks shall not be grouped as a substitute for larger rock.

Flat slab rock shall be laid on its vertical edge; except where it is laid like paving stone and the thickness of the rock equals the specified depth of the riprap course.

6. FILTER OR BEDDING

When the contract specifies filter, bedding or geotextile beneath the rock riprap, the designated material shall be placed on the prepared subgrade surface as specified. Compaction of filter or bedding aggregate will not be required, but the surface of such material shall be finished reasonably smooth and free of mounds, dips, or windrows.

7. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established in the contract, the quantity of each type of rock riprap placed within the specified limits will be computed to the nearest ton by actual weight. The volume of each type of filter or bedding aggregate will be measured within the specified limits and computed to the nearest cubic yard by the method of average cross-sectional end areas. For each load of rock riprap placed as specified, the Contractor shall furnish to the Engineer a statement-of-delivery ticket showing the weight, to nearest 0.1 ton.

Payment will be made at the contract unit price for each type of rock riprap, filter or bedding. Such payment will be considered full compensation for completion of the work.

Method 2 For items of work for which specific unit prices are established in the contract, the quantity of each type of rock riprap placed within the specified limits will be computed to the nearest 0.1 ton by actual weight. The quantity of each type of filter or bedding aggregate delivered and placed within the specified limits will be computed to the nearest 0.1 ton. For each load of rock riprap placed as specified, the Contractor shall furnish to the Engineer a statement-of-delivery ticket showing the weight, to the nearest 0.1 ton. For each load of filter or bedding aggregate, the Contractor shall furnish to the Engineer a statement-of-delivery ticket showing the weight to the nearest 0.1 ton.

Payment will be made at the contract unit price for each type of rock riprap, filter or bedding. Such payment will be considered full compensation for completion of the work.

Method 3 For items of work for which specific unit prices are established by the contract, the volume of each type of rock riprap and filter or bedding aggregate will be measured within the specified limits and computed to the nearest cubic yard by the method of average cross-sectional end areas.

Payment will be made at the contract unit price for each type of rock riprap, filter or bedding. Such payment will be considered full compensation for completion of the work.

Method 4 For items of work for which specific unit prices are established by the contract, the volume of each type of rock riprap, including filter and bedding aggregate, will be measured within the specified limits and computed to the nearest cubic yard by the method of average cross-sectional end areas.

Payment will be made at the contract unit price for each type of rock riprap, including filter and bedding. Such payment will be considered full compensation for completion of the work.

Method 5 For items of work for which specific unit prices are established by the contract, the quantity of each type of rock riprap placed within the specified limits will

be computed to the nearest ton by actual weight. For each load of rock for riprap placed as specified, the Contractor shall furnish to the Engineer a statement-of-delivery ticket showing the weight to the nearest 0.1 ton.

Payment will be made at the contract unit price for each type of rock riprap, including geotextile used for filter or bedding. Such payment will be considered full compensation for completion of the work.

Method 6 For items of work for which specific unit prices are established by the contract, the volume of each type of rock riprap will be measured within the specified limits and computed to the nearest cubic yard by the method of average cross-sectional end areas.

Payment will be made at the contract unit price for each type of rock riprap, including geotextile used for filter or bedding. Such payment will be considered full compensation for completion of the work.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 8.

No separate payment will be made for testing the gradation of the test pile. Compensation for testing will be included in the appropriate bid item for riprap.

GROUTED ROCK RIPRAP

1. APPLICABILITY

Construction Specification 62 is applicable to the placement of grouted rock riprap on channel slopes and other designated areas.

2. MATERIAL SPECIFICATIONS

Material Specifications [521](#), [522](#), [523](#), [531](#), [532](#), [533](#), [534](#), and [592](#) together with Construction Specification [31](#), [32](#) and [95](#) are complementary to Construction Specification 62.

3. ITEMS TO BE INCLUDED IN CONSTRUCTION SPECIFICATIONS AND DRAWINGS

- a. Complete plans and cross-sections clearly defining the grouted rock riprap requirements.
- b. Pay limits, where applicable.
- c. Gradation of rock.
- d. Gradation of filter or bedding materials, if used.
- e. Location of weep holes and pipe material for weep holes, if used.
- f. Placement tolerances.
- g. Design of grout mix together with the slump range and amount of air content.
- h. Type of cement.
- i. Type of admixtures, if any.
- j. Gradation of coarse aggregate.
- k. Designate equipment-placed or hand-placed rock.
- l. Designate if grout is to be placed or pumped.
- m. Method of measurement and payment.

4. DISCUSSION OF METHODS

a. Section 4, Placement of Rock Riprap

- (1) Method 1 is intended for use when rock placement operations that may cause some displacement of the filter or bedding materials is not critical. Access to the site for dumping by hauling and placing equipment is reasonable.

(2) Method 2 is intended for sites with limited access by hauling and placement equipment. This method should be considered when using geotextile filter materials and sharp angular rock so puncture of the geotextile can be minimized. Hand-placed operations should be considered on steeper slopes.

b. Section 12, Measurement and Payment

(1) Method 1 is intended for use when the volume of riprap and grout, together with the filter or bedding material when used, is computed as one quantity and paid for at the contract unit price for grouted rock riprap.

(2) Method 2 is intended for use when the volume of riprap, the volume of filter or bedding, the volume of concrete grout, and the area of geotextile are computed and paid as separate items.

(3) Method 3 is intended for use when the actual weight of rock and filter/bedding materials delivered is determined and paid to the nearest 0.1 ton, the grout volume is determined and paid to the nearest 0.1 cubic yard from batch volumes delivered, and the geotextile is determined and paid to the nearest square yard.

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete, "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

62. GROUTED ROCK RIPRAP

1. SCOPE

The work shall consist of furnishing, transporting, and the installation of grouted rock riprap revetments and blankets, including filter or bedding where specified.

2. MATERIALS

Rock for riprap shall conform to the requirements of Material Specification 523 or, if so specified shall be obtained from designated sources. It shall be free from dirt, clay, sand, rock fines and other materials not meeting the required gradation limits.

At least thirty (30) days prior to delivery of rock from other than designated sources, the Contractor shall designate, in writing, the source from which rock materials will be obtained and provide information satisfactory to the Engineer that the material meets contract requirements. The Contractor shall provide the Engineer free access to the source for the purpose of obtaining samples for testing. The size and grading of the rock shall be as specified in Section 13 of this specification.

Rock from approved sources shall be excavated, selected, and processed to meet the specified quality and grading requirements at the time the rock is installed.

When specified in Section 13 of this specification or, when requested by the Contracting Officer, a gradation quality control check shall be made by the Contractor and subject to inspection by the Engineer. The test shall be performed at the work site, in accordance to ASTM D 5519 Test Method B Size, Size-Range Grading, on a test pile of representative rock. The weight or size of the test pile shall be large enough to ensure a representative gradation of rock from the source and to provide test results within a five (5) percent accuracy.

Based on a specific gravity of 2.65 (typical of limestone and dolomite), and assuming the individual rock is shaped midway between a sphere and a cube, typical size/weight relationships are:

Sieve Size of Rock	Approximate Weight of Rock	Weight of Test Pile
16 inches	300 pounds	6000 pounds
11 inches	100 pounds	2000 pounds
6 inches	15 pounds	300 pounds

The results of the test shall be compared to the gradation required for the project. Test pile results that do not meet the construction specifications shall be cause for the rock to be rejected. The test pile that meets contract requirements shall be left on the job site as a sample for visual comparison. The test pile shall be used as part of the last rock riprap to be placed.

Filter or bedding aggregates when required, shall conform to Material Specification 521, unless otherwise specified.

Portland cement shall conform to the requirements of Material Specification 531 for the specified type.

Pozzolan. Unless otherwise specified in Section 13 of this specification, pozzolans conforming to Specification ASTM C 618, Class F, in amounts not to exceed 25 percent, based on absolute volume, may be substituted for an equivalent amount of portland cement in the grout mixture.

Aggregates shall conform to the requirements of material Specification 522, except that the grading for coarse aggregate shall be as specified in Section 13 of this specification.

Water shall be clean and free from injurious amounts of oils, acid, alkali, organic matter or other deleterious substances.

Air-entraining admixtures shall conform to the requirements of Material Specification 533.

Curing compound shall conform to the requirements of Material Specification 534.

Other admixtures, when required, shall be as specified in Section 13 of this specification.

Geotextiles shall conform to the requirements of Material Specification 592.

3. SUBGRADE PREPARATION

The subgrade surfaces on which the grouted rock riprap, filter, bedding or geotextile is to be placed shall be cut or filled and graded to the lines and grades shown on the drawings. When fill to subgrade lines is required, it shall consist of approved materials and shall conform to the requirements of the specified class of earthfill.

Rock riprap, filter, bedding or geotextile shall not be placed until the foundation preparation is completed and the subgrade surfaces have been inspected and approved.

4. PLACEMENT OF ROCK RIPRAP

Method 1 - Equipment-Placed Rock The rock riprap shall be placed by equipment on the surfaces and to the depths specified. The rock riprap shall be installed to the full section thickness in one operation and in such a manner as to avoid serious displacement of the underlying materials. The rock for riprap shall be delivered and placed in a manner that will ensure that the riprap in place shall be reasonably homogeneous with the larger rocks uniformly distributed and firmly in contact one to another with the smaller rocks and spalls filling the voids between the larger rocks. Some hand placing may be required to provide a neat and uniform surface.

Rock riprap shall be placed in a manner to prevent damage to structures. Hand placing will be required as necessary to prevent damage to any new and existing structures.

Method 2 - Hand-Placed Rock The rock riprap shall be placed by hand on the surfaces and to the depths specified. It shall be securely bedded with the larger rocks firmly in contact one to another without bridging. Spaces between the larger rocks shall be filled with smaller rocks and spalls. Smaller rocks shall not be grouped as a substitute for larger rock. Flat slab rock shall be laid on its vertical edge; except where it is installed like paving stone and the thickness of the rock equals the specified depth of the riprap section.

5. FILTER OR BEDDING

When the contract specifies filter, bedding or geotextile beneath the rock riprap, the designated material shall be placed on the prepared subgrade surface as specified. Compaction of filter or bedding aggregate will not be required, but the surface of such material shall be finished reasonably smooth and free of mounds, dips, or windrows.

6. DESIGN OF THE GROUT MIX

The mix proportions for the grout mix shall be as specified in the construction details in Section 13 of this specification. During installation, the Engineer may require adjustment of the mix proportions whenever necessary. The mix shall not be altered without the approval of the Engineer.

7. HANDLING AND MEASUREMENT OF GROUT MATERIALS

Materials shall be stockpiled and batched by methods that will prevent segregation or contamination of aggregates and ensure accurate proportioning of the mix ingredients.

Except as otherwise provided in Section 13 of this specification, cement and aggregates shall be measured as follows:

Cement shall be measured by weight or in bags of 94 pounds each. When cement is measured in bags, no fraction of a bag shall be used unless weighed.

Aggregates shall be measured by weight. Mix proportions shall be based on the batch weight of each aggregate saturated, surface-dry weight plus the weight of surface moisture it contains at the time of batching.

Water shall be measured by volume or by weight, to an accuracy within one (1) percent of the total quantity of water required for the batch.

Admixtures shall be measured within a limit of accuracy of plus or minus three (3) percent.

8. MIXERS AND MIXING

The mixer, when operating at capacity, shall be capable of combining the ingredients of the grout mix into a thoroughly mixed and uniform mass, and of discharging the mix with a satisfactory degree of uniformity.

The mixer shall be operated within the limits of the manufacturer's guaranteed capacity and speed of rotation.

The time of mixing after all cement and aggregates have been combined in the mixer shall be a minimum of one (1) minute for mixers having a capacity of one (1) cubic yard or less. For larger capacity mixers, the minimum time shall be increased fifteen (15) seconds for each cubic yard or fraction thereof of additional capacity. The batch shall be so charged into the mixer that some water will enter in advance of the cement and aggregates, with the balance of the mixing water introduced into the mixer before one-fourth (1/4) of the total minimum mixing time has elapsed.

When ready-mix grout is furnished, the Contractor shall furnish to the Engineer at the time of delivery a ticket showing the time of loading and the quantities of materials used for each load of grout mix delivered.

No mixing water in excess of the amount required by the approved job mix shall be added to the grout mix during mixing or hauling or after arrival at the delivery point.

9. CONVEYING AND PLACING

The grout mix shall be delivered to the site and placed within 1 1/2 hours after the introduction of the cement to the aggregates. In hot weather or under conditions contributing to accelerated stiffening of the concrete, the time between the introduction of the cement to the aggregates and complete discharge of the grout batch shall be a maximum of 45 minutes. The Engineer may allow a longer time provided the setting time of the grout is increased a corresponding amount by the addition of an approved set-retarding admixture. In any case, concrete shall be conveyed from the mixer to the final placement as rapidly as practicable by methods that will prevent segregation of the aggregates, loss of mortar, and/or displacement of the rock riprap.

Grout mix shall not be allowed to free fall more than five (5) feet unless suitable equipment is used to prevent segregation.

The grout mix shall not be placed until the rock riprap has been inspected and approved by the Engineer for the placement of grout.

Rock to be grouted shall be kept moist for a minimum of two (2) hours prior to grouting.

The rock riprap shall be flushed with water prior to placing the grout to remove the fines from the rock surfaces. The rock shall be kept moist prior to the grouting and

without placing in standing or flowing water. Grout placed on inverts or other nearly level areas may be placed in one operation. On slopes, the grout shall be placed in two (2) nearly equal applications consisting of successive lateral strips approximately ten (10) feet in width starting at the toe of the slope and progressing upward. The grout shall be delivered to the place of final deposit by approved methods and discharged directly on the surface of the rock, using a splash plate of metal or wood to prevent displacement of the rock directly under the grout discharge. The flow of grout shall be directed with brooms, spades or baffles to prevent grout from flowing excessively along the same path and to assure that all intermittent spaces are filled. Sufficient barring shall be conducted to loosen tight pockets of rock and otherwise aid in the penetration of grout to ensure the grout fully penetrates the total thickness of the rock blanket. All brooming on slopes shall be uphill. After the grout has stiffened, the entire surface shall be rebroomed to eliminate runs and to fill voids caused by sloughing. The surface finish, following the completion of grout installation, shall consist of 1/3 of the rock extended above the level of grout. The exposed rock will not have a plastered appearance.

After completion of any strip or panel, no individuals or equipment shall be permitted on the grouted surface for a period of twenty-four (24) hours. The grouted surface shall be protected from injurious action by the sun, rain, flowing water, mechanical injury, or other potential damaging activity.

10. CURING AND PROTECTION

The completed finished surface shall be prevented from drying for a minimum curing period of seven (7) days following placement. Exposed surfaces shall be maintained in a moist condition continuously for the seven (7) day curing period, or until curing compound has been applied as specified in this section. Moisture shall be maintained by sprinkling, flooding or fog spraying or by covering with continuously moistened canvas, cloth mats, straw, sand or other approved material. Water or moist covering shall be utilized to protect the grout during the curing process without causing damage to the grout surface by erosion or other mechanisms that may cause physical damage.

The grouted rock may be coated with an approved curing compound as an alternative method to maintaining a continuous moisture condition during the curing period. The compound shall be sprayed on the moist grout surfaces as soon as free water has disappeared and all surface finishing has been completed. The compound shall be applied at a minimum uniform rate of one (1) gallon per 175 square feet of surface and shall form a continuous adherent membrane over the entire surface. Curing compound shall not be applied to surfaces requiring bond to subsequently placed grout and/or concrete. If the membrane is damaged during the curing period, the damaged area shall be re-sprayed at the rate of application specified for the original treatment.

Grout mix shall not be placed when the daily minimum temperature is less than 40° F unless facilities are provided to ensure that the temperature of the materials is

maintained at a minimum temperature of 50° F and not more than 90° F during placement and the curing period. Grout mix shall not be placed on frozen surfaces. When freezing conditions prevail, rock to be grouted must be covered and heated to within a range of 50° F to 90° F for a minimum period of 24 hours prior to placing grouting materials.

11. INSPECTING AND TESTING FRESH GROUT

The grout material shall be checked and tested throughout the grouting operation. Sampling of fresh grout shall be conducted in conformance with ASTM C 172. The volume of each batch will be determined by methods prescribed in ASTM C 138.

The Engineer shall have free access to all parts of the Contractor's plant and equipment utilized for mixing and placing grout during the period of the contract. Proper facilities shall be provided for the Engineer to sample materials and view processes implemented in the mixing and placing of grout as well as for securing grout test samples. All tests and inspections shall be so conducted as a minimum of interference to the Contractor's operation occurs.

For ready-mixed grout, the Contractor shall furnish to the Engineer a statement-of-delivery ticket for each batch delivered to the site. The ticket shall provide as a minimum: weights in pounds of cement, aggregates (fine and coarse), water; weight in ounces of air-entraining agent; time of loading; and, the revolution counter reading at the time batching was started.

12. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established in the contract, the volume of grouted rock riprap, including filter layers or bedding, will be determined to the nearest cubic yard from the specified thickness shown on the drawings and the area on which acceptable placement has been installed. Payment for grouted rock riprap will be made at the contract unit price. Such payment will be considered full compensation for all labor, materials, equipment and all other items necessary and incidental to the completion of the grouted rock riprap, filter layers and bedding, and geotextile materials.

Method 2 For items of work for which specific unit prices are established in the contract, the volume of riprap and the volume of filter layers or bedding will be determined to the nearest cubic yard from the specified thickness shown on the drawings and the area on which acceptable placement has been installed. The volume of grout will be determined from the calculated batch volume and the number of mixed batches delivered to the site and placed in accordance with the specification. The area of geotextile will be determined to the nearest square yard from measurements of geotextile material installed according to the contract requirements. Payment will be made at the contract unit price for each type of rock riprap, filter or bedding, concrete grout, and geotextile. Such payment will be

considered full compensation for all labor, materials, equipment, and all other items necessary and incidental to the completion of the work.

Method 3 For items of work for which specific unit prices are established in the contract, the quantity of each type of rock riprap placed within the specified limits will be computed to the nearest 0.1 ton by actual weight. The quantity of each type of filter or bedding aggregate delivered and placed within the specified limits will be computed to the nearest 0.1 ton. For each load of rock riprap placed as specified, the Contractor shall furnish to the Engineer a statement-of-delivery ticket showing the weight to the nearest 0.1 ton. For each load of filter or bedding aggregate, the Contractor shall furnish to the Engineer a statement-of-delivery ticket showing the weight to the nearest 0.1 ton. The volume of grout will be determined from the calculated batch volume and the number of mixed batches delivered to the site and placed in accordance with the specifications and drawings. The area of geotextile will be determined to the nearest square yard from measurements of geotextile material installed according to the contract requirements. Payment will be made at the contract unit price for each type of rock riprap, filter or bedding, concrete grout, and geotextile. Such payment will be considered full compensation for all labor, materials, equipment and all other items necessary and incidental to the completion of the work.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 13 of this specification.

TREATMENT OF ROCK SURFACES

1. APPLICABILITY

Construction Specification 63 is applicable to the treatment of rock surfaces. Included are the cleaning and preparing of the surfaces and the furnishing and placing of the treatment materials. Where large volumes of concrete are involved or when desired, Construction Specification 32 may be used as an alternative to this specification. Treatment details would then be placed in construction details for Construction Specification 32.

2. MATERIAL SPECIFICATIONS

The following materials are complementary to Construction Specification 63:

- a. Portland Cement - Specification 531.
- b. Aggregate for Portland Cement Concrete - Specification 522
- c. Curing Compound - Specification 534

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Plan view showing location and extent of surface treatment.
- b. Details for cleaning and treatment of cracks, and dental excavation.
- c. Type of treatment, including design of mix, slump, air content, and special placement methods when required.
- d. Type of cement.
- e. Type of admixtures, include necessary material specifications.
- f. Gradation of coarse aggregate.
- g. Slope limitations for the finished surface(s), as determined by site topography, plasticity of available fill material, embankment zoning and other design considerations, stated as follows: "Except for small local areas, the slope of the finished surface shall not be steeper than ____ horizontal to ____ vertical. Steeper surfaces extending not more than ____ feet, measured vertically, will be permitted."
- h. Method of Curing and Protection in Section 8.
- i. Method of Measurement and Payment in Section 9.

4. DISCUSSION OF METHODS

a. Section 8, Curing and Protection

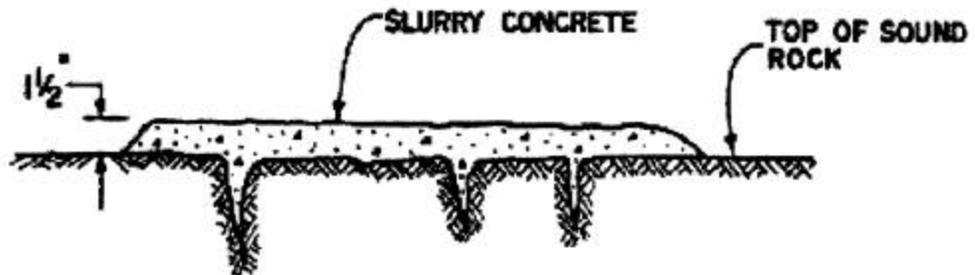

- (1) Method 1 Treatment of rock surfaces is intended to remove surface irregularities that could contribute to non-uniform installation of earth materials.
- (2) Method 2 Treatment of rock surfaces is an integral phase to insure blending and/or bonding of surface treatment and the proposed earth embankments. Water-tightness and the reduction of potential seepage paths are a major design consideration.

b. Section 9, Measurement and Payment

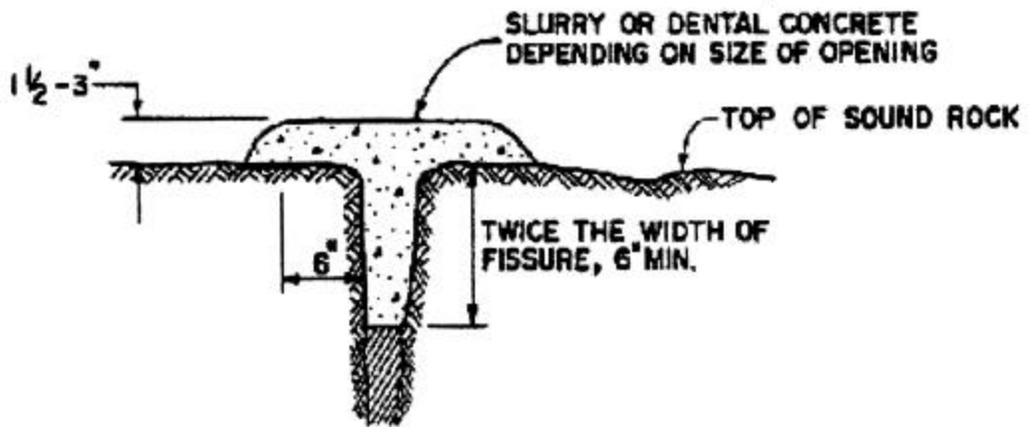

- (1) Method 1 is intended for use when the area to be treated is not fully definable and the full extent of treatment will need to be determined at the time of installation. This method applies to rock surfaces that have significant irregularities and are not readily determined prior to installation.
- (2) Method 2 is intended for use when the area to be treated is clearly definable and the extent of treatment has been determined. This method applies to rock surfaces that can be viewed and extent of treatment will not vary.

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

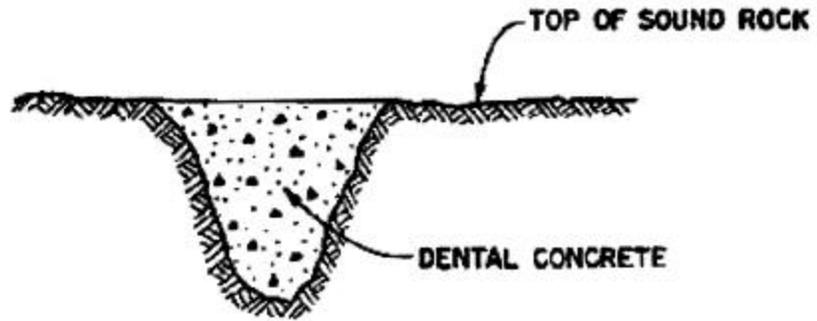

TYPICAL TREATMENTS OF ROCK SURFACES

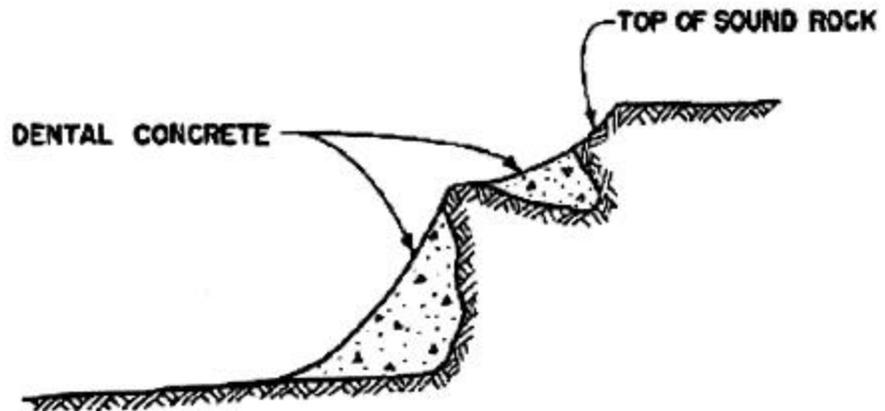

1.) THIN SURFACE CRACKS

2.) OPEN FISSURES

3.) HOLES OR SOLUTION CHANNELS

4.) OVERHANGS AND IRREGULAR SURFACES

CONSTRUCTION SPECIFICATION

63. TREATMENT OF ROCK SURFACES

1. SCOPE

This work shall consist of preparing and cleaning the designated rock surfaces, including the specified dental excavation, and the furnishing and placing of the specified treatment material for either dental or slurry grout.

2. MATERIALS

Portland cement shall conform to the requirements of Material Specification 531 for the type specified in Section 10 of this specification.

Pozzolans. Unless otherwise specified in Section 10 of this specification, pozzolans conforming to the ASTM C 618, Class C or F, may be used in amounts not to exceed 25 percent, based on absolute volume, to substitute for an equal amount of portland cement in the concrete grout mixture.

Aggregates shall conform to the requirements of Material Specification 522, except that the grading for coarse aggregate shall be as specified in Section 10 of this specification.

Water shall be clean and free from injurious amounts of oil, acid, alkali, organic matter, or other deleterious substances.

Admixtures, when specified, shall be of the type and quality specified in Section 10 of this specification.

Curing compound shall conform to the requirements of Material Specification 534.

3. PREPARATION AND CLEANING

After excavation of the overburden has been completed, the rock surfaces shall be thoroughly cleaned and dewatered. All loose rock, ledges, and overhangs exposed during preparation of the rock surfaces shall be removed. Surfaces exceeding the slope limitations specified in Section 10 of this specification shall be eliminated by excavation or by filling with concrete as described in Section 7 of this specification.

Dental excavation shall consist of the removal of all soil and soft or loose rock from cracks, fissures, holes, and solution channels exposed during excavation activities. The extent of the dental excavation shall be as shown on the drawings with on-site adjustments as determined by the Engineer.

The surfaces shall be cleaned by air-water cutting, water jetting, wire brush scrubbing, or other suitable methods determined necessary to obtain an acceptable surface. No surface treatment material shall be applied until rock surfaces have been inspected and approved.

Rock surfaces shall be free of standing or running water during the placement of surface treatment material.

4. DESIGN OF-SURFACE TREATMENT MATERIAL

The treatment material and mix proportions shall be as specified in Section 10 of this specification. During the surface treatment operation, the Engineer may require adjustment of the mix proportions. The mix shall not be altered without the approval of the Engineer.

5. HANDLING AND MEASUREMENT OF MATERIALS

Materials shall be stockpiled and batched by methods that will prevent segregation or contamination of aggregates and insure accurate measurement and proportioning of the mix ingredients.

Except as otherwise provided in Section 10 of this specification, cement and aggregates shall be measured as follows:

- a. Cement shall be measured by weight or in bags of 94 pounds each. When cement is measured in bags, no fraction of a bag shall be used unless properly weighed.
- b. Aggregates shall be measured by weight. Mix proportions shall be based on saturated, surface-dry weights. The batch weight of each aggregate shall be required saturated, surface-dry weight plus the weight of the surface moisture it contains at the time of batching.
- c. Water shall be measured, by volume or weight, to an accuracy within one (1) percent of the total quantity of water required for the batch.
- d. Admixtures shall be measured within a limit of accuracy of three (3) percent.

6. MIXERS AND MIXING

The mixer, when operating at capacity, shall be capable of combining the ingredients of the concrete into a thoroughly mixed and uniform mass and of discharging the mix with a satisfactory degree of uniformity.

The mixer shall be operated within the limits of the manufacturer's guaranteed capacity and speed of rotation.

The time of mixing, after all cement and aggregates are combined in the mixer, shall be a minimum of one (1) minute for mixers having a capacity of one (1) cubic yard or less. For larger capacity mixers, the minimum time shall be increased fifteen (15) seconds for each cubic yard or fraction thereof of additional capacity. The batch shall be so charged into the mixer that some water will enter in advance of the

cement and aggregates, with the balance of the mixing water introduced into the mixer before one-fourth (1/4) of the total mixing time has elapsed.

No mixing water in excess of the amount required by the approved job mix shall be added to the grout mix during mixing or hauling or after arrival at the delivery point.

7. CONVEYING AND PLACING

Surface treatment materials shall be delivered to the site and placed within 1 1/2 hours after the introduction of the cement to the aggregates. In hot weather or under conditions contributing to accelerated stiffening of the concrete, the time between the introduction of the cement to the aggregates and complete discharge of the concrete shall be a maximum of 45 minutes. The Engineer may allow a longer period, provided the setting time of the concrete is increased a corresponding amount by the addition of an approved set-retarding admixture. In any case, concrete shall be conveyed from the mixer to the final placement as rapidly as practical by methods that will prevent segregation of the aggregates and/or loss of mortar.

Concrete shall not be allowed to free fall more than five (5) feet unless suitable equipment is used to prevent segregation.

Surface treatment materials shall not be placed until the rock surfaces have been inspected and approved by the Engineer.

All cracks, fissures, solution channels, and other surfaces within the designated area shall be treated as shown on the drawings. Surfaces to be treated shall be kept moist for a minimum of two (2) hours prior to treatment.

Concrete shall be filled against any specified remaining rock surfaces that exceed the slope limitations and shall be shaped so that no portion of the finished surface exceeds these limitations.

Material placed in cracks, fissures, and solution channels shall be consolidated by vibration, spading, or tamping as necessary to assure complete filling of the void.

8. CURING AND PROTECTION

Method 1 The surface of treatment materials shall be prevented from drying for a minimum curing period of seven (7) days after placement. Exposed surfaces shall be maintained in a moist condition continuously for the seven (7) day curing period, or until curing compound has been applied as specified in this section. Moisture shall be maintained by sprinkling, flooding or fog spraying or by covering with continuously moistened canvas, cloth mats, straw, sand or other acceptable material. Water or moist covering shall be utilized to protect the concrete treatment during the curing process without causing damage to the treatment surface by erosion or other mechanisms that may cause physical damage.

The concrete treatment material may be coated with an approved curing compound as an alternative method to maintaining a continuous moisture condition during the curing period. The compound shall be sprayed on the moist treatment surfaces as soon as free water has disappeared and all surface finishing has been completed. The compound shall be applied at a minimum uniform rate of one (1) gallon per 175-square feet of surface and shall form a continuous adherent membrane over the entire treated surface. Curing compound shall not be applied to surfaces requiring bond to subsequently placed grout and/or concrete. If the membrane is damaged during the curing period, the damaged area shall be re-sprayed at the rate application specified for the original treatment.

Backfilling operations shall not commence for a minimum period of 24 hours following the placement of concrete treatment, unless otherwise specified.

Method 2 A minimum earth cover of 1 1/2 feet depth shall be placed and compacted before the rock surface treatment material (concrete) has established an initial set. The earth cover may be placed on the concrete with a dragline, hoe, or else bladed onto the treated surface by lightweight dozer or similar equipment operating from a covered and compacted surface. Compaction shall be accomplished by pneumatic-tired equipment or by an alternative method that will provide an equivalent density.

Use With Either Method No backfill material shall be placed until the treated surfaces have been inspected and approved by the Engineer.

Surface treatment materials shall not be placed when the daily minimum temperature is less than 40° F unless facilities are provided to insure that the temperature of the materials is maintained at a minimum temperature of 50° F and not greater than 90° F during placement and the curing period. Concrete treatment material shall not be placed on frozen surfaces. When freezing conditions prevail, rock surfaces to be treated must be covered and heated to within a range of 50° F and 90° F for a minimum period of 24 hours prior to placing concrete treatment materials.

9. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established in the contract, the area of rock surfaces to be prepared, cleaned and treated will be measured to the nearest square yard within the limits established by the Engineer. The volume of surface treatment material placed within the established limits will be computed to the nearest 0.1 cubic yard of concrete placed. Payment will be made at the contract unit price for surface preparation, cleaning, and installation of surface treatment materials. Such payment shall constitute full compensation of all labor, equipment, materials and all other items necessary and incidental to the completion of the work.

Method 2 For items of work for which specific unit prices are established in the contract, the area of rock surfaces to be prepared, cleaned and treated will not be

measured. The volume of surface treatment materials delivered and properly installed to treat rock surfaces will be determined to the nearest 0.1 cubic yard. Areas to be treated are shown on the drawings with the final extent of rock surface treatment to be determined by the Engineer. The volume of any waste or otherwise unsuitable material will be determined by procedures established by the Engineer and deducted from the volume of concrete delivered to the site. Payment will be made at the contract unit price for surface preparation, cleaning, and installation of surface treatment materials. Such payment shall constitute full compensation of all labor, equipment, materials and all other items necessary and incidental to the completion of the work.

All Methods For each load of concrete delivered to the site for placement as rock treatment material, the Contractor shall furnish to the Engineer a delivery ticket at the time of delivery which shall provide as a minimum: Weights in pounds of cement, aggregates (fine and coarse), pozzolan (if used), water; weight in ounces of air-entraining agent; time of loading; and, the revolution counter reading at the time batching was started.

Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 10 of this specification.

WIRE MESH GABIONS AND MATTRESSES
TWISTED (WOVEN) OR WELDED MESH

1. APPLICABILITY

Construction Specification 64 is applicable to the installation of wire mesh gabion baskets and mattresses, including bedding, filter or geotextile where specified.

2. MATERIAL SPECIFICATIONS

Material Specification [523, Rock for Riprap](#), is complementary to this specification.

Material Specification [521, Aggregates for Drainfill and Filters](#), is complementary to this specification.

Material Specification [592, Geotextile](#), is complementary to this specification.

Construction Specification [95, Geotextile](#), is complementary to this specification.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Complete drawings showing alignment, layout, size of baskets or mattresses required, interior support details, lacing, connecting or fastening plans as applicable, and any other related appurtenances or details.
- b. Gabions designated as basket or mattress, as appropriate. Type of gabion construction: Twisted or Welded Mesh.
- c. Specify in Section 8 if alternate ring fasteners as recommended by the manufacturer, are to be allowed for basket interconnection and closure of tops. The specification only allows the use of alternative ring fasteners for the assembly of empty gabion baskets or mattresses. If it is determined that the use of these fasteners can provide a minimum strength of 1,400 lb. per linear foot for gabions and 900 lb. per linear foot for gabion mattresses; then Section 8 of this specification may be used to allow their use to join gabions together and to close the lids of gabions. The manufacturer's recommendations are to be followed concerning the proper interlocking of fasteners and their spacing to attain the required strength.
- d. Specify the type of wire (plain, galvanized, or PVC coated), if specific design requirements need to be met, coating color, and any special requirements such as different wire size or mesh openings, etc., as applicable, in Section 8. (Note that in Table 2 only PVC coated gabion mattresses are specified.)
- e. Details of bedding, filter material and/or geotextile; including gradation for materials, compaction requirements of materials, class of geotextile and any special requirements, if required. Refer to the respective construction specifications as applicable. Both types of gabions perform best when placed on relatively smooth and unyielding foundations. A coarse aggregate or a stone

leveling course can be successfully used under gabions to enhance good support and grade control.

- f. Source of rock and pre-qualification of other materials as appropriate.
- g. Rock size if different than that specified.
- h. Requirements for concrete cap, if applicable, including location and placement details. Include and refer to Construction Specifications 31, 32, or 33 as necessary.
- i. Rockfill and lid closure requirements for gabions placed on a slope to serve as a chute with flow down the top surface. It is very important that these gabions be filled as densely as possible to avoid movement and distortion during design flow events.
- j. The specified batter to the front face of vertical gabion walls. A maximum wall batter of 6 degrees is recommended (1 horizontal to 10 vertical). Where possible, design stepped faced gabion walls instead of vertical faced walls.
- k. Method of measurement and payment in Section 8.

4. DISCUSSION OF METHODS

a. Section 7, Measurement and Payment

- (1) Method 1 is used when payment is to be made for gabions or mattresses and rock filler. Bedding, filter or geotextile are to be paid under a separate item.
- (2) Method 2 is used when payment is made for gabions or mattresses and rock filler including the bedding or filter and geotextile. Include a description of the subsidiary items in Section 8 of this specification and in the items of work and construction details of the appropriate companion construction specification.
- (3) Method 3 is used when payment is to be made for gabion mattresses and rock filler. Bedding, filter or geotextile are to be paid under a separate item of work.
- (4) Method 4 is used when payment is made for completed gabion mattresses and rock filler including the bedding or filter and geotextile. Include a description of the subsidiary items in Section 8 and in the items of work and construction details of the appropriate companion construction specification.

When specifications are prepared using electronic procedures and all but one of the methods is deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

64. WIRE MESH GABIONS AND MATTRESSES **TWISTED (WOVEN) OR WELDED MESH**

1. SCOPE

The work shall consist of furnishing, assembling and installing rock filled wire mesh gabion baskets and mattresses.

2. TYPES

Gabions shall consist of rectangular wire mesh formed containers filled with rock. Gabions will conform to one of the following types:

Woven Mesh. Non-raveling double twisted hexagonal wire mesh, consisting of two wires twisted together in two 180 degree turns.

Welded Mesh. Welded-wire mesh with a uniform square or rectangular pattern and a resistance weld at each intersection. The welded wire connections shall conform with the requirements of ASTM A 185, including wire smaller than W1.2 (0.124 in.); except that the welded connections shall have a minimum average shear strength of 70% and a minimum shear strength of 60% of the minimum ultimate tensile strength of the wire.

Gabions. Gabions shall be furnished as baskets or mattresses, as specified in Section 8. Baskets and mattresses shall be fabricated within a dimension tolerance of plus or minus 5 percent.

Baskets. Baskets have a height of 12 inches or greater.

Mattresses. Mattresses have a thickness of 12 inches and less.

3. MATERIALS

Gabions shall be fabricated, assembled and installed in accordance with the nominal wire sizes and dimensions found in Tables 1 and 2, using the following materials, unless otherwise specified in Section 8.

Wire for fabrication and assembly shall be hot-dipped galvanized. The wire shall have a minimum tensile strength of 60,000 psi. Galvanized steel wire shall conform to ASTM A 641, Class 3, Soft Temper.

TABLE 1 (Minimum Requirements) *
GABION BASKETS--Height 12, 18, or 36 Inches; Length as Specified

Type of Wire	Mesh Size Inches	Wire Diameter Inches	PVC Coating Inches	Total Diameter Inches	Galvanized Coating (oz./SF)
Woven Mesh	3-1/4 x 4-1/2	0.118	None	0.118	0.80
	3-1/4 x 4-1/2	0.105	0.02	0.145	0.80
Selvage		0.153	None	0.153	0.80
		0.132	0.02	0.172	0.80
Lacing and Internal Connecting Wire		0.086	0.02	0.126	0.70
Welded Mesh	3 x 3	0.118	None	0.118	0.80
	3 x 3	0.105	0.02	0.145	0.80
Spiral Binder		0.105	0.02	0.145	0.80

TABLE 2 (Minimum Requirements) *
GABION MATTRESSES--Height 6, 9, or 12 Inches; Length as Specified

Type of Wire	Mesh Size Inches	Wire Diameter Inches	PVC Coating Inches	Total Diameter Inches	Galvanized Coating (oz./SF)
Woven Mesh	2-1/2 x 3-1/4	0.086	0.02	0.126	0.70
Selvage		0.105	0.02	0.145	0.80
Lacing and Internal Connecting Wire		0.086	0.02	0.126	0.70
Welded Mesh	1-1/2 x 3	0.080	0.02	0.120	0.70
Spiral Binder		0.105	0.02	0.145	0.80

*NOTE: The wire sizes and PVC coating thickness shown are nominal sizes.

The wire sizes include the galvanizing coating thickness.

When Epoxy or Polyvinyl Chloride (PVC) coated wire is specified in Section 8, the galvanized wire shall be coated by fusion bonded epoxy; or fusion bonded, extruded, or extruded and bonded PVC material. The wire coating shall be colored black, gray, green or silvery; and the initial properties of the PVC coating shall meet the following requirements:

- (a) Specific Gravity. In the range of 1.30 to 1.40, ASTM D 792.
- (b) Abrasion Resistance. The percentage of weight loss shall be less than 12%, when tested according to ASTM D 1242, Method B at 200 cycles, CSI-A Abrader Tape, 80 Grit.
- (c) Brittleness Temperature. Not higher than 15° F, ASTM D 746.
- (d) Tensile Strength. Extruded Coating (not less than 2,980 psi., ASTM D 412). Fusion Bonded Coating (not less than 2,275 psi., ASTM D 638).
- (e) Modulus of Elasticity. Extruded Coating (not less than 2,700 psi. at 100 percent strain, ASTM D 412). Fusion Bonded Coating (not less than 1980 psi. at 100 percent strain, ASTM D 638).
- (f) Ultraviolet Light Exposure. A test period of not less than 3000 hours, using apparatus type E at 63 C, ASTM G 23.
- (g) Salt Spray Test. A test period of not less than 3000 hours, ASTM B 117.

After the exposure to ultraviolet light and the salt spray test as specified above, the PVC coating shall not show cracks, blisters, splits, nor noticeable change of coloring (surface chalk). In addition, the specific gravity shall not change more than six (6) percent, resistance to abrasion shall not change more than ten (10) percent, tensile strength shall not change more than 25 percent, and modulus of elasticity shall not change more than 25 percent from their initial values.

The wire sizes shown in Tables 1 and 2 are the size of the wire after galvanizing and before coating with PVC.

Spiral binders are the standard fastener for welded-mesh gabion baskets and mattresses, and shall be formed from wire meeting the same quality and coating thickness requirements as specified for the gabion baskets and mattresses.

Alternate fasteners for use with wire mesh gabions, such as ring fasteners, shall be formed from wire meeting the same quality and coating thickness requirements as specified for the gabions.

Standard fasteners and alternate fasteners must provide a minimum strength of 1,400 lb. per lineal foot for gabion baskets and 900 lb. per lineal foot for gabion mattresses. When used to interconnect gabion baskets or mattresses with PVC coating, ring fasteners shall be made of stainless steel and spiral fasteners will be

PVC coated. All fasteners shall meet all of the closing requirements of the gabion manufacturer in addition to any requirements specified in Section 8.

Rock shall conform to the quality requirements in Material Specification 523, unless otherwise specified in Section 8. At least 85 percent of the rock particles, by weight, shall be within the predominant rock size range.

Gabion Basket or Mattress Height	Predominant Rock Size Inches	Minimum Rock Dimension Inches	Maximum Rock Dimension Inches
12, 18, or 36 Inch Basket	4 to 8	4	9
6, 9, or 12 Inch Mattress	3 to 6	3	7

At least 30 days prior to delivery to the site, the Contractor shall inform the Engineer in writing of the source from which the rock will be obtained, and include the test data and other information by which the material was determined by the Contractor to meet the specification. The Contractor shall provide the Engineer free access to the source for the purpose of obtaining samples for testing and source approval.

Bedding or filter material, when specified, shall meet the gradation shown on the plans or as specified in Section 8, and the requirements of Material Specification 521. Geotextile, when specified, shall conform to the requirements specified in Section 8, and those of Material Specification 592.

4. FOUNDATION PREPARATION

The foundation on which the gabions are to be placed shall be cut or filled and graded to the lines and grades shown on the drawings. Surface irregularities, loose material, vegetation, and all foreign matter shall be removed from foundations. When fill is required, it shall consist of materials conforming to the specified requirements. Gabions and bedding or specified geotextiles shall not be placed until the foundation preparation is completed, and the subgrade surfaces have been inspected and approved by the Engineer.

Compaction of bedding or filter material will be required as specified in Section 8. The surface of the finished material shall be to grade and free of mounds, dips or windrows. Geotextile shall be installed in accordance with the requirements of Construction Specification 95.

5. ASSEMBLY AND PLACEMENT

Unless otherwise specified in Section 8, the assembly and placement of gabions shall be in accordance with the following procedures:

Assembly. Rotate the gabion panels into position and join the vertical edges with fasteners for gabion assembly. Where lacing wire is used, wrap the wire with alternating single and double half-hitches at intervals between four (4) to five (5) inches. Where spiral fasteners are used for welded-wire mesh, crimp the ends to secure the spirals in place. Where ring type alternate fasteners are used for basket assembly, install the fasteners at a maximum spacing of 6 inches. Use the same fastening procedures to install interior diaphragms where they are required.

Interior diaphragms will be required where any inside dimension exceeds three (3) feet. Diaphragms will be installed to assure that no open intervals are present that exceed three (3) feet.

Placement. Place the empty gabions on the foundation and interconnect the adjacent gabions along the top, bottom, and vertical edges using lacing wire. Wrap the wire with alternating single and double half-hitches at intervals between four (4) to six (6) inches. Unless otherwise specified in Section 8, lacing wire will be the only fastener allowed for interconnecting woven mesh gabions. Spiral fasteners are commonly used for the assembly and interconnection of welded mesh gabions. Spirals are screwed down at the connecting edges then each end of the spiral is securely tied down to prevent unraveling. Lacing may be used as needed to supplement the interconnection of welded mesh gabions, and the closing of lids.

Interconnect each layer of gabions to the underlying layer of gabions along the front, back, and sides. Stagger the vertical joints between the gabions of adjacent rows and layers by at least one-half of a cell length.

6. FILLING OPERATION

After adjacent empty woven wire gabion units are set to line and grade and common sides properly connected, they shall be placed in straight line tension and stretched to remove any kinks from the mesh and to gain a uniform alignment. Welded-mesh gabions do not require stretching. Staking of the gabions may be done to maintain the established proper alignment prior to the placement of rock. No stakes shall be placed through geotextile material. Connecting lacing wire and other fasteners, as allowed, shall be attached during the filling operation to preserve the strength and shape of the structure.

Internal connecting cross-tie wires shall be placed in each unrestrained gabion cell greater than 18 inches in height, including gabion cells left temporarily unrestrained. Two internal connecting wires shall be placed concurrently with rock placement, at each 12-inch interval of depth. In woven mesh gabions these cross-ties will be placed evenly spaced along the front face and connecting to the back face. All cross-tie wires shall be looped around two mesh openings and each wire end shall be secured by a minimum of five 180 degree twists around itself after looping.

In welded mesh gabions these cross-ties or stiffeners will be placed across the corners of the gabions (at 12 inches from the corners) providing diagonal bracing. Lacing wire or preformed hooked wire stiffeners may be used.

The gabions shall be carefully filled with rock, either by machine or hand methods, ensuring alignment, avoiding bulges, and providing a compact mass that minimizes voids. Machine placement will require supplementing with hand work to ensure the desired results. The cells in any row shall be filled in stages so that the depth of rock placed in any one cell does not exceed the depth of rock in any adjoining cell by more than 12 inches. Along the exposed faces, the outer layer of stone shall be carefully placed and arranged by hand to ensure a neat, compact placement with a uniform appearance.

The last layer of rock shall be uniformly leveled to the top edges of the gabions. Lids shall be stretched tight over the rock filling using only approved lid closing tools as necessary. The use of crowbars or other single point leverage bars for lid closing is prohibited as they may damage the baskets. The lid shall be stretched until it meets the perimeter edges of the front and end panels. The gabion lid shall then be secured to the sides, ends, and diaphragms with spiral binders, approved alternate fasteners, or lacing wire wrapped with alternating single and double half-hitches in the mesh openings.

Any damage to the wire or coatings during assembly, placement and filling shall be repaired promptly in accordance with the manufacturer's recommendations or replaced with undamaged gabion baskets.

7. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established in the contract; the volume of rock will be measured within the neat lines of the gabion structure and computed to the nearest cubic yard. Payment for gabions will be made at the contract unit price, and includes the wire mesh and rock. Such payment will be considered full compensation for all labor, materials, equipment and all other items necessary and incidental to completion of the work.

Method 2 For items of work for which specific unit prices are established in the contract, the volume of the gabions will be measured within the neat lines of the gabion structure and computed to the nearest cubic yard. Payment for the gabions will be made at the contract unit price, and includes the wire mesh, rock and specified bedding material or geotextile. Such payment will be considered full compensation for all labor, materials, equipment and all other items necessary and incidental to the completion of the work.

Method 3 For items of work for which specific unit prices are established in the contract, the surface area will be measured within the neat lines of the gabion mattress structure and computed to the nearest square yard. Payment for the gabion mattress will be made at the contract unit price, and includes the wire mesh

and rock. Such payment will be considered full compensation for all labor, materials, equipment and all other items necessary and incidental to the completion of the work.

Method 4 For items of work for which specific unit prices are established in the contract, the surface area will be measured within the neat lines of the gabion mattress structure and computed to the nearest square yard. Payment for the gabion mattress will be made at the contract unit price, and include the wire mesh, rock and specified bedding material or geotextile. Such payment will be considered full compensation for all labor, materials, equipment and all other items necessary and incidental to the completion of the work.

All Methods The following provisions apply to all methods of measurement and payment. Unless otherwise specified in Section 8, no deduction in volume will be made for any void or embedded item. Compensation for any item of work described in the contract, but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Each item and the items to which they are made subsidiary are identified in Section 8 of this specification.

WATER CONTROL GATES

1. **APPLICABILITY**

Construction Specification 71 is applicable to the installation of gates for the purpose of water control, including slide gates, flap gates and radial gates.

2. **MATERIAL SPECIFICATIONS**

Material Specifications [571](#), [572](#), and [573](#) are complementary to Construction Specification 71. Table A-71 is a guide to selection of metal water control gates. When fabricated wooden gates are required for special applications, a material specification tailored to the specific job is usually more appropriate.

3. **ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS**

- a. Plans, elevations and sections showing location of gates and type and size of openings.
- b. Types of gates and applicable material specifications.
- c. Class of gate (seating and unseating heads expressed as a numerical symbol). Example: Class 40-10 denotes a seating head of 40 feet and an unseating head of 10 feet.
- d. Type of frame (flat, spigot, flange, flange with spigot) and details of the method of attaching the gate to the structure or pipe. Include thimble details, when required, together with designation of type of thimble (Types: E, F, C, L, Flange and Bell, or Flange and Flare).
- e. Special gate requirements (self-contained, nonrising stem, flush-bottom opening, etc.); include material requirements for fabricated metal gates if other than steel is required.
- f. Type and capacity of gate stems, hoists, lifts, stem guides, stem housings, couplings, sleeves and other appurtenances.
- g. Paint systems to be used in shop and field painting. (Refer to Construction Specification [82, Cleaning and Painting Metalwork](#)).
- h. Special gate operating requirements, particularly if the gate is intended to operate in other than the fully open or fully closed position. Example: Gate will be required to operate in a partially open position under a full head.

4. **DISCUSSION OF METHODS**

No alternative methods are included.

TABLE A-71

GUIDE TO SELECTION OF METAL WATER CONTROL GATES

Type of Gate	Application	Frequency of Use	<u>Types of Gates Satisfactory for Exposure Condition</u>		
			Fresh Water or Slight Pollution	Moderate Pollution (Domestic & Agricultural Sewage, & Industrial Waste)	Extreme Pollution, Sea Water, Brackish Water
Slide	Drainage gates; Canal headgates	Frequent Infrequent	MLS-1&2, MMS-1 MMS-1, MHS-1	MHS-2	MHS-3
	Sediment pool drainage gate	Infrequent	MMS-2, MHS-1	MHS-2	MHS-3
	Reservoir water supply	Frequent	MMS-2, MHS-1	MHS-2	MHS-3
	Intake gates	Infrequent	MHS-1, MHS-2	MHS-3	MHS-3
Flap	Accessible gravity outlets		MMF-1, MLF-1	MHF-2	MHF-3
	Inaccessible gravity outlets		MHF-1, MMF-1	MHF-2	MHF-3
	Pump outlets, not subject to slamming		MHF-1, MMF-1	MHF-2	MHF-3
	Pump outlets, subject to slamming		MHF-1R	MHF-2R	MHF-3R

CONSTRUCTION SPECIFICATION

71. WATER CONTROL GATES

1. SCOPE

The work shall consist of furnishing and installing water control gates including gate stems, hoists, lifts and other appurtenances.

2. MATERIALS

The gates furnished shall conform to the requirements of Material Specifications [571](#), [572](#), and [573](#), as appropriate, and as specified in Section 8 of this specification and on the drawings. All gates shall be furnished complete with hoisting equipment and other specified appurtenances.

3. INSTALLING GATES

The Contractor shall install the gates in a manner that will prevent leakage around the seats and binding of the gates during normal operation.

Surfaces of metal against which concrete will be placed shall be free from oil, grease, loose mill scale, loose paint, surface rust, and other debris or objectionable coatings.

Anchor bolts, thimbles and spigot frames shall be secured in true position within the concrete forms and maintained in alignment during concrete placement.

Concrete surfaces against which rubber seals will bear or against which flat frames or plates are to be installed shall be finished to provide a smooth and uniform contact surface.

When a flat frame is installed against concrete, a layer of concrete mortar shall be placed between the gate frame and the concrete.

When a gate is attached to a wall thimble, a mastic or resilient gasket shall be applied between the gate frame and the thimble, in accordance with the recommendations of the gate manufacturer.

For radial gates, wall plates, sills and pin brackets shall be adjusted and fastened by grouting and bolting after the gates have been completely assembled in place.

4. INSTALLING HOISTS AND LIFTS

Gate stems, stem guides and gate lifts shall be carefully aligned so that the stem shall be parallel to the guide bars or angles on the gate frame following installation.

5. RADIAL GATE SEALS

The rubber seals for radial gates shall be installed so that the seals contact the walls or wall plates throughout the entire gate length when the gate is in the closed position.

6. OPERATIONAL TESTS

After the gate(s) and hoist(s) (or lifts) have been installed, they shall be cleaned, lubricated and otherwise serviced by the Contractor in accordance with the manufacturer's instructions. The Contractor shall test the gate and hoist by operating the system several times throughout its full range of operation. The Contractor shall make any changes and/or adjustments necessary to insure satisfactory operation of the complete gate system.

7. MEASUREMENT AND PAYMENT

The number of each type, size and class of gate will be counted. Payment for furnishing and installing each type, size and class of gate shall be made at the contract unit price for that type, size and class of gate. Such payment will constitute full compensation for all labor, equipment, materials and all other items necessary and incidental to the completion of the work including furnishing and installing anchor bolts and all specified appurtenances and fittings.

Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and items to which they are made subsidiary are identified in Section 8 of this specification.

METAL FABRICATION AND INSTALLATION

1. APPLICABILITY

Construction Specification 81 is applicable to the construction of items of metalwork not covered by other specifications. It is applicable to such items as trash guards, anti-vortex hoods and baffles, flashboard guides, and similar structures or parts. It is not applicable to the installation of concrete reinforcing steel, water control gates, fences, wells, piles or pipe conduits.

2. MATERIAL SPECIFICATIONS

Material Specification 581 and 582 and Construction Specification 82 are complementary to Construction Specification 81.

3. ITEMS TO BE INCLUDED IN CONSTRUCTION SPECIFICATIONS AND DRAWINGS

- a. Detailed drawings as necessary to show the dimensions and method of fabrication and erecting the item or structure.
- b. For aluminum, the alloy to be used in the work if other than specified in Material Specification 581. Alloys specified for use should be limited to those for which ASCE Specifications for Structures of Aluminum Alloy are available. Such specifications are published in Section A of the Aluminum Construction Manual of The Aluminum Association.
- c. Type of steel if other than structural quality. Use "commercial" or "merchant" quality only for small parts where the strength is not a major design consideration. Examples: Non-critical angles and other shapes less than three (3) inches in maximum dimension of Section; shear plates for construction joints in concrete; small trash rack parts; and, other similar metal features.
- d. Details of connections showing sizes and number of bolts; sizes, kinds and dimensions of welds; and sizes and number of rivets.
- e. Designation of items to be galvanized or painted and designation of paint systems to be used.
- f. Ordering data listed in the material specifications, as appropriate, including such items as:
 - (1) Type, kind, size, hardness and length of bolts.
 - (2) Class, grade, condition and finish of castings.
 - (3) Type, composition, hardness, size and form of other materials.

- g. Methods of measurement and payment, if the standard specification includes more than one method.

4. DISCUSSION OF METHODS

a. Section 6, Measurement and Payment

- (1) Method 1 is intended for use when the metalwork is a minor portion of the contract and consists largely of items that would normally be fabricated by the Contractor.
- (2) Method 2 is intended for use when the metalwork is a significant portion of the contract.
- (3) Method 3 is intended for use when the metalwork includes individual items of significant scope or complexity or which would usually be procured from outside sources or fabricated for the contractor by others.

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

81. METAL FABRICATION AND INSTALLATION

1. SCOPE

The work shall consist of furnishing, fabricating and erecting metalwork, including the metal parts and fasteners of the composite structures.

2. MATERIALS

Unless otherwise specified, materials shall conform to the requirements of Material Specification [581, Metal](#). Steel shall be structural quality unless otherwise specified. Castings shall be thoroughly cleaned and subjected to careful inspection before installation. Finished surfaces shall be smooth and true to assure proper fit. Galvanizing shall conform to the requirements of Material Specification [582, Galvanizing](#).

3. FABRICATION

Fabrication of structural steel shall conform to the requirements of "Specification for the Design, Fabrication and Erection of Structural Steel for Buildings (Riveted, Bolted and Arc-Welded Construction)," American Institute of Steel Construction.

Fabrication of structural aluminum shall conform to the requirements in the 'Aluminum Design Manual', available from The Aluminum Association.

4. ERECTION

The frame of metal structures shall be installed true and plumb. Temporary bracing shall be placed wherever necessary to resist all loads to which the structure may be subjected, including those applied by the installation and operation of equipment. Such bracing shall be left in place as long as may be necessary for safety.

As erection progresses the work shall be securely bolted up, or welded, to resist all dead load, wind and erection stresses. The Contractor shall furnish such installation assisting bolts, nuts and washers as may be required.

No riveting or welding shall be performed until the structure is stiffened and properly aligned.

Rivets driven in the field shall be heated and driven with the same care as those driven in the shop.

All field welding shall be performed in conformance to the requirements for shop fabrication, except those that expressly apply to shop conditions only.

5. PROTECTIVE COATINGS

Items specified to be galvanized shall be completely fabricated for field assembly before the application of the zinc coatings. Galvanized items shall not be cut, welded or drilled after the zinc coating is applied.

Items specified to be painted shall be painted in conformance to the requirements of Construction Specification 82 for the specified paint systems.

6. MEASUREMENT AND PAYMENT

Method 1 The work will not be measured. Payment for metal fabrication and installation will be made at the contract lump sum price in the contract. Such payment will constitute full compensation for all labor, equipment, materials and all other items necessary and incidental to the completion of the work, including connectors and appurtenances such as rivets, bolts, nuts, pins, studs, washers, hangers and weld metal.

Method 2 The weight of metal installed complete in place shall be determined to the nearest pound. Unless otherwise specified, the weight of metal shall be computed by the method specified in Section 3 of the "Code of Standard Practice for Steel Buildings and Bridges," American Institute of Steel Construction, except that the following unit weights shall also be used, as appropriate, as the basis of computation:

<u>Material</u>	<u>Unit Weight (lbs./ft.³)</u>
Aluminum alloy	173.0
Bronze or copper alloy	536.0
Iron, malleable	470.0
Iron, wrought	487.0

Payment for furnishing, fabricating and installing metalwork will be made at the contract unit price for the specified types of labor, materials, equipment and all other items necessary and incidental to the completion of the work.

Method 3 The work will not be measured. Payment for furnishing, fabricating and installing each item of metalwork will be made at the contract price for that item. Such payment will constitute full compensation for all labor, equipment, materials and all other items necessary and incidental to the completion of the work, including connectors and appurtenances such as rivets, bolts, nuts, pins, studs, washers, hangers and weld metal.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 7 of this specification.

PAINING METALWORK

1. **APPLICABILITY**

Construction Specification 82 is applicable to the painting of metalwork including structural metal, water control gates, piping, pumps and other metal equipment and machinery.

The durability of paint films on metal depends upon the exposure condition, the types of paints used, the thickness of the coating and the method of preparing the metal surface prior to the application of primers and paint. To a large extent the type of paint required is dictated by the exposure condition and the required surface preparation is dictated by the type of paint to be applied. Each paint system specifies the type and quality of paint, the number of coats or minimum paint film thickness required and the finish (gloss, semi-gloss, flat, etc.).

The paint systems are not equivalent optional methods. Each paint system is designed to provide protection for a particular exposure condition or to produce a particular finished appearance or both. The criteria for selection of the appropriate paint system and surface preparations for that finish are summarized in Table A-82 of these instructions.

Where a minor amount of painting is to be performed, and it is not required for protection, use a simple note on the drawings rather than Construction Specification 82.

2. **MATERIAL SPECIFICATIONS**

Material Specification [583, Coal Tar-Epoxy Paint](#), is complementary to Construction Specification 82 when Paint System F is specified. References to the Steel Structures Paint Council (SSPC) for surface preparation are summarized. Refer to SSPC for full text as appropriate. There are no other material specifications complementary to this specification. Any material requirements are to be specified in Section 10.

3. **ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS**

- a. Indicate by notes on the drawings, the surfaces and items to be painted.
- b. Designate the paint system (by letter) to be used for painting each indicated item. If all metalwork is to be painted by the same paint system, one standard note to that effect will be sufficient.
- c. Waiver of the requirement that the Contractor furnish a plan and materials list, if the plan is not necessary.
- d. Provide color requirements, finish (gloss, semi-gloss, etc.) and any special requirements as appropriate.

- e. Instructions for painting, surface preparation or other special conditions or methods not covered by the standard specification.
- f. Surface preparation for needed maintenance painting may be limited to those spots or areas having loss of protection by corrosion and/or wearing surfaces. A clean sound paint surface provides a good base for added layers.
- g. Provide tinting requirements as appropriate. Various coatings have a unique tolerance for pigmentation. Under or over-pigmentation can produce poor cover quality (hide) and less than desirable performance.
- h. Note in Section 10 if the Contractor is to provide paint specification information to the Engineer which is to be shared with the owners to use for their responsibility for operation and maintenance.

4. DISCUSSION OF METHODS

Select the method or methods for surface preparation that are appropriate for the durability and length of service required. Refer to Table A-82 for surface preparation recommendations. The quality of surface preparation diminishes as the Method number increases and the expected surface life is reduced accordingly. The small cost increase in selecting a higher quality preparation can significantly reduce O&M costs and untimely coating failure.

TABLE A-82**PAINT SYSTEMS FOR METALWORK**

Paint System	Type of Paint Material	Description and Conditions for Use	Example Applications	Surface Preparation
A	Alkyd Primer (Type 1) Alkyd Enamel (Type 2) Gloss or Semi-gloss (Type 3)	A good interior and exterior system. It is not intended for humid or damp environments. System A should not be applied to surfaces that constantly sweat or are immersed in water. It will chalk or oxidize when subjected to sunlight.	Interior and exterior surfaces of buildings, piping, pumps, and machinery above operating floors, doors, frames, tanks, etc.	Method 2 or 3, Commercial Blast or Brush-off Blast
B	Single package moisture cured urethane primer (Type 9) Alkyd Enamel (Type 2) Gloss or Semi-gloss (Type 3)	Similar to the qualities of System A. Urethane primer allows system to be applied over poorly prepared surfaces particularly in areas where proper preparation is difficult or impractical. It is a good system for repainting over old existing paint for rehabilitation.	Exterior or interior surfaces of buildings, piping, pumps, and machinery above operating level. Good rehabilitation system when preparation is minimal.	Method 2 or 3, Commercial Blast or Brush-off Blast
C	Epoxy Polyamide (Type 4) Epoxy Polyamide (Type 5)	An excellent system for constant or intermittent immersion in salts or fresh water. Excellent for surfaces exposed to constant humidity and sweating. Excellent chemical resistance and available in almost all colors. Will chalk or oxidize when exposed to sunlight.	Trash racks and guards or flap gates, stop logs and guides, pumps, piping, machinery, storage tanks, etc.	Method 1, near white Blast.
D	Epoxy Polyamide Primer (Type 4) Epoxy Polyamide (Type 5) Acrylic Polyurethane Gloss (Type 6) or Semi-gloss (Type 7)	Same as System C except is topcoated with acrylic polyurethane. Not recommended for immersed metals. Excellent interior or exterior in humid or arid environment. High abrasion resistance. Excellent color and gloss retention (15 times greater than Systems A, B, or C). Excellent on steel that sweats. Available in either gloss or semi-gloss. Should be considered for long-term exposure to sunlight or when esthetics are a factor.	Exterior surfaces of building such as drains, overflows, gutters and piping exposed to either humid or arid conditions. Any metal items that gather condensation and/or have high exposure to sunlight. Interior surfaces such as walls, ceilings, structural steel, equipment, piping, etc.	Method 2 or 3, Commercial Blast or Brush-off Blast

TABLE A-82 (Continued)

PAINT SYSTEMS FOR METALWORK

Paint System	Type of Paint Material	Description and Conditions for Use	Example Applications	Surface Preparation
E	Single package moisture cured Urethane Primer (Type 9) Acrylic Polyurethane Gloss (Type 6) or Semi-gloss (Type 7)	Good system for dry humid environments. Excellent color and gloss retention. Cannot be used for coating immersed metals and is not as good as System D in constant moisture. Excellent long-term esthetics.	Structural steel, siding, doors, frames, piping, machinery, storage tanks, etc.	Method 2 or 3, Commercial or Brush-off Blast
F	Coal Tar Epoxy (Type 10)	Excellent in constant or intermittent immersion in salt or fresh water. Excellent also for buried steel surfaces. Available in black only – will change to brown when exposed to sunlight, but sunlight does not adversely effect performance. Excellent chemical resistance and dependability exhibited in extensive use throughout the water and wastewater treatment industry. NOTE: Galvanized surfaces require a pre-treatment vinyl acid wash primer prior to applying paint, as noted in Type 8 Paints. Sandblasting or aged galvanized surfaces do <u>not</u> require a vinyl wash treatment.	Trash guards, water control gates, pipes, steel piling, stop logs and guides, water tanks, flumes, etc.	Method 1, Near White Blast
G	Epoxy Polyamide Primer (Type 4) Single package Moisture Cured Urethane (Type 9)	Excellent system for repair of damaged galvanized metal in humid or arid environments. Will provide protection for surfaces exposed to constant humidity and sweating.	Trash guards, CMP, stop logs and guides, and other galvanized metalwork.	Method 4 or 5, Hand Tool or Solvent Clean
H	Vinyl Acid Wash Treatment (Type 8)	For use as a pre-treatment wash for galvanized and non-ferrous metals that require painting.	Trash guards, CMP, stop logs and guides, gutters, downspouts, and other galvanized or non-ferrous metals.	Steam Clean with TSP, or Solvent clean, regularly changing rags.

TABLE A-82. PAINT SYSTEMS FOR METALWORK (Continued)

- a. All surface preparation referred to herein shall be performed in accordance with SSPC (Steel Structures Painting Council).
- b. All painting and coating shall be performed per SSPC Good Painting Practices and paint manufacturer's recommendations.
- c. Coated steel subjected to potable water service shall be coated in accordance with American Water Works Association (AWWA) provisions and directions. Said coatings shall meet United States National Sanitation Foundation (US-NSF) requirements.
- d. When special protective coatings or other specific painting recommendations are necessary, refer to the Paint Manual, United States Department of Interior (USDI), Bureau of Reclamation or paint manufacturer's data.
- e. Surface preparation indicated is the method that will provide coating quality appropriate for exposure conditions. Methods that produce a greater or a lesser quality can be chosen to produce the quality of work that is necessary. Hand Tool Cleaning (Method 4) and Solvent Cleaning (Method 5) are applicable for field applications, small areas requiring coating, or in making repairs to factory coatings.

CONSTRUCTION SPECIFICATION

82. PAINTING METALWORK

1 SCOPE

The work shall consist of cleaning metal surfaces and applying paints and protective coatings.

2. PAINT

For the purpose of this specification, paints and coatings shall be designated by types as defined below.

Materials for systems requiring two (2) or more coats shall be supplied by the same manufacturer.

Unless otherwise specified and prior to application, the Contractor shall furnish in writing to the Engineer for approval a plan outlining procedures proposed for painting metalwork and a list of materials including name of manufacturer, pertinent product identification names and numbers and product data sheets. Data shall reflect the requirements set forth in this section.

Type 1 Alkyd Primer. Alkyd based, rust inhibitive primer. Primer shall be lead and chromate free. Primer shall have a minimum of 54 percent solids by volume. Color availability shall be red, gray, and white. Primer shall be able to be applied satisfactory at 2.0 to 3.0 mils dry-film thickness in one coat.

Type 2 Alkyd Enamel (Gloss). Alkyd based enamel shall be lead free. Alkyd enamel shall have a minimum of 49 percent solids by volume. Alkyd enamel shall be able to be applied satisfactory at 2.0 to 3.0 mils dry-film thickness in one coat. Finish shall be gloss.

Type 3 Alkyd Enamel (Semi-gloss). Alkyd based enamel shall be lead free. Alkyd enamel shall have a minimum of 55 percent solids by volume. Alkyd enamel shall be able to be applied satisfactory at 2.0 to 3.0 mils dry-film thickness in one coat. Finish shall be semi-gloss.

Type 4 Epoxy Polyamide Primer. Epoxy polyamide primer shall be lead and chromate free. Epoxy primer shall have a minimum of 56 percent solids by volume. Epoxy primer shall be able to be applied satisfactory at 4.0 to 6.0 mils dry-film thickness in one coat. Color availability shall be red, gray, and white. Epoxy primer shall conform to AWWA Standard C 210 and AWWA Standard D 102.

Type 5 Epoxy Polyamide (intermediate or finish). Epoxy polyamide shall be lead free. Epoxy shall have a minimum of 56 percent solids by volume. Epoxy shall be able to be applied satisfactory at 4.0 to 6.0 mils dry-film thickness in one coat. Finish shall be semi-gloss. Epoxy finish shall conform to AWWA C 210 and AWWA D 102.

Type 6 Acrylic Polyurethane (Gloss). Acrylic polyurethane shall be lead free. Acrylic polyurethane shall have a minimum of 74 percent solids by volume. Polyurethane shall be able to be applied satisfactory at 3.0 to 5.0 mils dry-film thickness in one coat. Finish shall be gloss.

Type 7 Acrylic Polyurethane (Semi-gloss). Acrylic polyurethane shall be lead free. Acrylic polyurethane (semi-gloss) shall have a minimum of 58 percent solids by volume. Polyurethane shall be able to be applied satisfactory at 3.0 to 5.0 mils dry-film thickness in one coat. Finish shall be semi-gloss.

Type 8 Vinyl Acid Wash Treatment. Pre-treatment primer for galvanized and non-ferrous metal. Pre-treatment primer shall have a minimum of 8 percent solids by volume. The applied dry-film thickness of pre-treatment primer shall not exceed 0.5 mil. Steel primed with pre-treatment primer shall be top coated within six to eight hours in humid conditions.

Type 9 Single Package Moisture Cured Urethane Primer. Urethane primer shall have a minimum of 50 percent solids by volume. Primer shall be able to be applied satisfactory at 2.0 to 3.0 mils dry-film thickness in one coat. Color shall be metallic aluminum.

Type 10 Coal Tar Epoxy. Coal tar epoxy shall have a minimum of 75 percent solids by volume and conform to the requirements of NRCS Material Specification [583 Coal Tar Epoxy Paint](#) (Steel Structures Paint Council PS No. 16, Type I). Coal tar epoxy shall be able to be applied satisfactory at 8.0 to 15.0 mils dry-film thickness in one coat.

3. TINTING

Tinting shall not be performed in the field unless otherwise specified.

4. SURFACE PREPARATION

Surfaces to be painted shall be thoroughly cleaned prior to the application of paint or coatings. Surface preparations required by this specification are as designated by SSPC (Steel Structures Painting Council) and are summarized by the Methods listed in this section.

Method 1 Near White Blast (SSPC-SP10). All surfaces to be coated shall be prepared by removing all grease and oil using steam cleaning or solvent cleaning methods per Method 5. After degreasing is completed, sand or grit blasting shall be performed to remove all dirt, rust, mill scale and/or other foreign material or residue. The cleaned, finished surface shall be a minimum of 95 percent free of all visible foreign material and/or residue.

Method 2 Commercial Blast (SSPC-SP6). All surfaces to be coated shall be prepared by removing all grease and oil using steam cleaning or solvent cleaning methods per Method 5. After degreasing is completed, sand or grit blasting shall be

performed to remove all dirt, rust, mill scale or other foreign material or residue. The cleaned, finished surface shall be a minimum of 67 percent free of all visible foreign material or residue.

Method 3 Brush-off Blast Cleaning (SSPC-SP7). All surfaces to be coated shall be prepared by removing all grease and oil using steam cleaning or solvent cleaning methods per Method 5. After degreasing is completed, and or grit blasting shall be performed to remove dirt, rust, mill scale or other foreign material or residue. Tightly adherent mill scale, rust and paint are considered tightly adherent if they cannot be removed by lifting with a dull putty knife.

Method 4 Hand Tool Cleaning (SSPC-SP2). All surfaces to be coated shall be prepared by removing all oil or grease using steam cleaning or solvent cleaning methods per Method 5. After degreasing is completed, non-power hand tools shall be used to remove loose, detrimental foreign material. Adherent mill scale, rust and paint need not be removed.

Method 5 Solvent Cleaning (SSPC-SP1). Surfaces to be coated shall be prepared by removing all visible oil, grease, soil, drawing and cutting compounds and other soluble contaminants from surfaces with solvents or commercial cleaners using various methods of cleaning such as wiping, dipping, steam cleaning or vapor degreasing.

5. PAINT SYSTEMS

For the purposes of this specification, systems of painting and coating metalwork will be designated as defined in this section.

Paint System A shall consist of the application of one (1) primer coat of Type 1 and two (2) or more coats of Type 2 (gloss) or Type 3 (semi-gloss) to provide a minimum dry-film thickness of 6.0 mils.

Paint System B shall consist of the application of one (1) primer coat of Type 9 and two (2) or more coats of Type 2 (gloss) or Type 3 (semi-gloss) to provide a minimum dry-film thickness of 6.0 mils.

Paint System C shall consist of the application of one (1) coat of Type 4 and one (1) or more coats of Type 5 to provide a minimum dry-film thickness of 8.0 mils.

Paint System D shall consist of the application of one (1) coat of Type 4 primer, one (1) coat of Type 5 and one (1) coat of Type 6 (gloss) or Type 7 (semi-gloss) to provide a minimum dry-film thickness of 11.0 mils.

Paint System E shall consist of the application of one (1) coat of Type 9 and one (1) coat of Type 6 (gloss) or Type 7 (semi-gloss) to provide a minimum dry-film thickness of 5.0 mils.

Paint System F shall consist of the application of two (2) coats of Type 10 at a dry-film thickness of 8.0 mils. per coat. Total system shall provide a minimum dry-film thickness of 16.0 mils.

Paint System G shall consist of the application of two (2) coats of Type 4 and two (2) coats of Type 9 paint. Total system shall provide a minimum dry-film thickness of 14.0 mils.

6. APPLICATION OF PAINT

Surfaces shall be painted immediately after preparation or within the same day as prepared with a minimum of one (1) coat of the primer type specified. Remaining surfaces not required to be painted shall be protected against contamination and damage during the cleaning and painting operation.

Paints shall be thoroughly mixed immediately prior to application.

After erection or installation of the metalwork, all damage to shop applied coating shall be repaired and all bolts, nuts, welds and field rivet heads shall be cleaned and painted with one coat of the specified priming paint.

Except on surfaces accessible only to spray equipment, initial priming coats shall be applied by brush. All other coats may be applied by brush or spray. Each coat shall be applied in such a manner as to produce a paint film of uniform thickness with a rate of coverage within the guidelines and limits recommended by the paint manufacturer and as outlined in Section 2 of this specification.

The drying time between coats shall be as prescribed by the paint manufacturer, but not less than that required for the paint film to thoroughly dry. The elapsed time between coats in Paint System F shall not exceed 24 hours. If for any reason the critical re-coat time is exceeded, the coated surface shall be treated with the manufacturer's recommended tackifier solvent or brush blasted to roughen the surface.

The finished surface of each coat shall be free from runs, drops, ridges, laps or excessive brushmarks and shall present no variation in color, texture and finish.

The surface of each dried coat shall be cleaned as necessary before application of the next coat.

7. ATMOSPHERIC CONDITIONS

Paint application shall not be performed when the temperature of the item to be painted or the surrounding air is less than 50° F. Painting shall be performed only when the humidity and temperature of the surrounding air and the temperature of the metal surfaces are such that evaporation rather than condensation will result during the period of time required for application and drying. The surface shall be dry and a minimum of 5° F above the dew point. Surfaces protected from adverse

atmospheric conditions by special cover, heating or ventilation shall remain so protected until the paint is thoroughly dry.

8. TESTS

Dry-film thickness on ferrous metal shall be determined by the use of a non-destructive magnetic instrument such as an Elcometer or Mikrotest gauge. Instruments shall have been calibrated within one month prior to use. Film thickness on non-ferrous metal shall be determined with film gauges during the application process. Systems with film thickness less than specified shall be brought into conformance by the application of one or more additional coats of the specified material.

9. PAYMENT

For items of work for which lump sum prices are established in the contract, payment will be made as the work proceeds, after presentation of invoices by the Contractor supporting actual related costs and evidence of the charges of suppliers, subcontractors, and other for supplies furnished and work completed. If the total of such payments is less than the lump sum contract price for this item, the unpaid balance will be included in the next appropriate contract payment. Payment of the lump sum contract price will constitute full compensation for completion of the work.

Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 10 of this specification.

TIMBER FABRICATION AND INSTALLATION

1. APPLICABILITY

Construction Specification 83 is applicable to all types of timber construction (except pile driving or the use of round timber) that are normally an integral part of structures designed and installed under agency programs. Supplementary specifications will be required for works of a special nature, such as bridges or buildings.

2. MATERIAL SPECIFICATIONS

Material Specifications [581](#), [582](#), [584](#) and [585](#) and Construction Specification [84](#) are complementary to Construction Specification 83.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Plans and dimensions of all structural elements.
- b. Complete details of all connections including number, type and size and kind of nails or spikes or bolts with nuts if the design requires that these be specified; depth of embedment of screws and pins, etc.
- c. For lumber and timber, specify:
 - (1) Stress grade.
 - (2) Species according to standard commercial name.
 - (3) Heartwood requirements or other special requirements.
 - (4) Nominal size and dress requirements (rough or dressed).
 - (5) Preservative treatment, if required. (Refer to ASTM D 1760 for guidance to type of treatment.)
 - (6) Applicable grading rule, including the name of the agency that sponsors the rule (such as National Hardwood Lumber Association), the paragraph number and year of issue.
- d. For plywood and chipboard, specify:
 - (1) Number of plies, width and length of sheet.
 - (2) Species or group according to PS 1.
 - (3) Grade
 - (4) Type (exterior, interior)
 - (5) Finished thickness

- (6) Finish requirements (such as sanded or unsanded).
- e. Designation of surfaces to be painted.
- f. Special instructions concerning cutting of treated lumber or timber, if such operations are to be allowed.

4. DISCUSSION OF METHODS

a. Section 6, Measurement and Payment.

- (1) Method 1 is intended for use in cases where the quantities of lumber and timber are large and the measurement of structural elements is feasible.
- (2) Method 2 is considered more appropriate for structures of moderate size.
- (3) Method 3 provides a flexible method of payment when there are some structure units that can be paid for as completed structures and also structures that lend themselves to partial payment on a linear foot basis.

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

83. TIMBER FABRICATION AND INSTALLATION

1. SCOPE

The work shall consist of the construction of timber structures and timber portions of composite structures.

2. MATERIALS

Structural timber and lumber shall conform to the requirements of Material Specification 584. **Treated timber and lumber** shall be impregnated with the specified type and quantity of preservative and in the manner specified in Material Specification 585.

Hardware, except cast iron, shall be galvanized as specified for iron and steel hardware in Material Specification 582. Unless otherwise specified, structural steel shapes, plates and rods shall not be galvanized. Nuts, driftbolts, dowels and screws shall be either wrought iron or steel.

Steel bolts shall conform to the requirements of ASTM A 307. When galvanized or zinc-coated bolts are specified, the zinc coating shall conform to the requirements of Material Specification 582.

Washers shall be ogee gray iron castings or malleable iron castings unless washers cut from medium steel or wrought iron plate are specified on the drawings or in Section 7 of this specification. Cast washers shall have a thickness equal to the diameter of the bolt and a diameter equal to four (4) times the thickness. The thickness for plate washers shall be equal to one-half (1/2) the diameter of the bolt, and the sides of the square shall be equal to four (4) times the diameter of the bolt. Holes in washers shall have a maximum diameter of one-eighth (1/8) inch larger than the diameter of the bolt. Split ring connectors, tooth ring connectors and pressed steel shear plate connectors shall be manufactured from hot-rolled, low carbon steel conforming to the requirements of ASTM A 711, Grade 1015. Malleable iron shear plate connectors and spike grid connectors shall be manufactured in conformance with the requirements of ASTM A 47, Grade No. 35018. All connectors shall be of approved design and the type and size specified.

Structural shapes, rods and plates shall be structural steel conforming to the requirements of Material Specification 581. No welds will be permitted in truss rods or other main members of trusses or girders.

3. WORKMANSHIP

All framing shall be true and exact. Timber and lumber shall be accurately cut and assembled to a close fit and shall have even bearing over the entire contact surfaces. No open or shimmed joints will be accepted. Nails and spikes shall be driven with just sufficient force to set the heads flush with the surface of the wood. Deep hammer marks in wood surfaces shall be considered evidence of poor workmanship and may be sufficient cause for rejection of the work.

Holes for round driftpins and dowels shall be bored with a bit one-sixteenth inch smaller in diameter than that of the driftpin or dowel to be installed. The diameter of holes for square driftpins or dowels shall be equal to one side of the driftpin or dowel. Holes for lag screws shall be bored with a bit not larger than the body of the screw at the base of the thread.

Washers shall be used in contact with all bolt heads and nuts that would otherwise be in contact with wood. Cast iron washers shall be used when the bolt will be in contact with earth. All nuts shall be checked or burred effectively with a pointed tool after finally tightened.

Unless otherwise specified, surfacing, cutting and boring of timber and lumber shall be completed prior to treatment. If field cutting or field repair of treated timber and lumber is approved, all cuts and abrasions shall be carefully trimmed and coated with two paint on or swab-applied applications of a wood preservative containing not less than 5 percent (by weight) pentachlorophenol. A copper metal solution of 2 percent (by weight) of copper naphthenate may be used as a replacement for pentachlorophenol, which is a controlled substance. After timber assembly, any unfilled holes shall be plugged with tightly fitting wooden plugs that have been treated with preservative as specified.

4. HANDLING AND STORING MATERIALS

All timber and lumber stored at the site of the work shall be neatly stacked on supports a minimum of 12 inches above the ground surface and protected from the weather by suitable covering(s). Untreated material shall be staked and stripped to permit free circulation of air between the tiers and courses. Treated timber may be close-staked. The ground surface for the stockpile of timber and lumber shall be free of weeds and rubbish. The use of cant hooks, peavies, or other pointed tools, except end hooks will not be permitted in the handling of structural timber and/or lumber. Treated timber shall be handled with rope slings or other methods that will prevent the breaking or bruising of outer fibers, or penetration of the surface in any manner.

5. PAINTING

Except as otherwise specified, surfaces designated for painting shall be prepared and painted in accordance with Construction Specification [84](#).

6. MEASUREMENT AND PAYMENT

Method 1 The unit of measurement of lumber and timber will be the number of thousand feet board measure (MBM) of each type, size, species and grade of lumber and timber installed in the completed structure. The quantity of each type, size, species and grade will be computed from the nominal dimensions and actual lengths of the pieces in the completed structure and will not include waste timber used for erection purposes) such as falsework or temporary sheeting and bracing) or

any portion of any pile or other round timber. The total quantity of lumber and timber in each type, size, species and grade will be computed to the nearest 0.01 MBM.

The unit of measurement of plywood will be the number of square feet of each type, species, grade and thickness installed in the completed structure.

Payment for each type, size, species and grade of lumber and timber will be made at the contract unit price for that type, size, species and grade. Payment for each type, species, grade and thickness of plywood will be made at the contract unit price for that type, species, grade and thickness. Such payment will be considered full compensation for completion of the work.

Method 2 No measurement of material quantities will be made. Payment for each structure, complete in place, will be made at the contract lump sum price for that structure. Such payment will be considered full compensation for completion of the work.

Method 3 For items of work for which specific unit prices are established in the contract, measurement and payment for each structure unit, except those for which a linear foot payment is established, will be counted and payment made at the contract unit price. Items for which a linear foot payment is established will be measured to the nearest linear foot and payment will be made at the contract unit prices as appropriate. Such payment will be considered full compensation for completion of the work.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 7 of this specification.

INSTRUCTIONS FOR USE OF CONSTRUCTION SPECIFICATION 84

PAINING WOOD

1. APPLICABILITY

Construction Specification 84 is applicable to the exterior painting of wood materials.

2. MATERIAL SPECIFICATIONS

There are no material specifications complementary to Construction Specification 84.

3. ITEMS TO BE INCLUDED IN CONSTRUCT SPECIFICATIONS AND DRAWINGS

- a. Surfaces to be painted.
- b. Instructions for tinting if colors other than white are required.
- c. Paint and primer to be used if other than specified in Section 2.
- d. Number of paint and/or primer coats if other than specified in Section 4.

4. DISCUSSION OF METHODS

No methods are included.

NOTE: When ASTM or other applicable reference standards or specifications are available, reference to Federal Specifications will be replaced.

CONSTRUCTION SPECIFICATION

84. PAINTING WOOD

1. SCOPE

The work shall consist of cleaning and preparing wood surfaces and applying protective paint coatings.

2. MATERIALS

Unless otherwise specified in Section 7 of this specification, painting materials shall meet the following requirements:

Exterior paint primer shall conform to the requirements of Federal Specification TT-P-25.

Exterior oil paint shall conform to the requirements of Federal Specification TT-P-102. Unless otherwise specified, the color shall be white. The second coat of exterior oil paint may be thinned with mineral spirits conforming to the requirements of ASTM D 235 or with pure gum turpentine. The amount of thinner shall not exceed one (1) pint per gallon of paint.

When tinting is required, it shall be accomplished by the addition of pigment-in-oil tinting colors conforming to the requirements of Federal Specification TT-P-381.

3. SURFACE PREPARATION

All surfaces to be painted/primed shall be thoroughly cleaned prior to the application of paint/primer. Pitch pockets and knots shall be scraped and sealed with a shellac varnish conforming to the requirements of ASTM D 360. Previously painted surfaces shall be scraped and brushed to remove any checked or blistered paint and all excess chalk.

4. APPLICATION OF PAINT/PRIMER

Surfaces shall be clean and dry during paint/primer application. No paint/primer shall be applied until the prepared surfaces have been inspected and approved for paint/primer application.

Surfaces of new wood shall be painted with one (1) brush coat of exterior primer paint and two brush coats of exterior oil paint unless otherwise specified in Section 7 of this specification.

Paints/primers shall be thoroughly mixed at the time of application.

Each paint and primer coat shall be applied in such a manner as to produce a coating film of uniform thickness with a finished surface free of runs, drops, ridges, laps or excessive brush marks. The minimum drying time between applications shall be as prescribed by the manufacturer of the paint/primer and not prior to the previous paint/primer application being thoroughly dry.

The surface of each dried coating shall be cleaned as necessary before application of the next coat.

The first coat of exterior oil paint shall be tinted off-color by the addition of three (3) ounces of an appropriate tinting color per gallon of paint.

5. ATMOSPHERIC CONDITIONS

Unless otherwise specified in Section 7 of this specification or by the manufacturer of the coating products, paint and primer shall not be applied when the temperature of the wood surface or of the surrounding air is less than 45° F. Coatings shall not be applied when atmospheric conditions result in moisture condensation on the surface to be painted/primed. Surfaces protected from atmospheric conditions by special cover or enclosure, heating or ventilation shall remain to provide full protection until the paint/primer is thoroughly dry.

6. PAYMENT

For items of work for which specific lump sum prices are established in the contract, payment for priming and painting wood will be made at the contract lump sum price. Such payment will be full compensation for furnishing, preparing the surfaces, and applying all coating materials to wood surfaces designated to be painted including labor, tools, equipment, materials and all other items necessary and incidental to the completion of the work.

Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the item to which they are made subsidiary are identified in Section 7 of this specification.

INSTRUCTION FOR USE OF CONSTRUCTION SPECIFICATION 91

CHAIN LINK FENCE

1. APPLICABILITY

Construction Specification 91 is applicable to the installation of chain link fences.

2. MATERIAL SPECIFICATIONS

No material specifications are complementary to Construction Specification 91.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Plan showing the location and extent of fences including location of gates, corners, pull posts and end points.
- b. Dimensions of the fence including post spacing, clearance from ground and height of fence.
- c. Details of posts and assemblies:
 - (1) Types of post and top rails if other than specified in Section 2.
 - (2) Line post detail showing height of post, depth of embedment.
 - (3) Details of corner post assembly, pull post, and corner post, including embedment, top rail connections, tension wire detail, braces, trusses, etc.
 - (4) Show diameters of embedment items.
 - (5) Special anchor requirements, if any.
- d. Dimensions of gate opening (clear opening between inside faces of the gate posts).
- e. Dimensions of gates and type if other than specified in Section 2.
- f. Required appurtenances such as locks with number of keys, barbed wire arms, barbed wire, post tops, etc.
- g. Type, mesh, and gauge of chain link fabric, if other than specified in Section 2.
- h. If the fence materials are to be PVC coated, the following information should be included in the Items of Work and Construction Details:
 - (1) Specify PVC coating for the fence materials.
 - (2) Specify desired standard color of PVC Coating (See ASTM F 934) if other than black is to be used.

4. DISCUSSION OF METHODS

a. Section 5, Measurement and Payment

(1) Method 1 is intended for use when gates are a minor part of the work item.

(2) Method 2 is intended for use when gates form a substantial part of the work item or when gates must be installed in existing fences.

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

91. CHAIN LINK FENCE

1. SCOPE

The work shall consist of furnishing and installing chain link fencing complete with all posts, braces, gates and all other appurtenances.

2. MATERIALS

The materials for the chain link fence shall be as follows:

Galvanized

Chain link fence fabric shall conform to the requirements of ASTM A 392, 2-inch mesh, and 9-gauge galvanized steel wire. Zinc coating shall be Class 2.

Posts and fence framework shall conform to the requirements of ASTM F 1043 Group 1A, for Heavy Industrial Fence. Coatings shall be a Type A galvanized coating for both internal and external surfaces. Steel pipe posts shall conform to the requirements of ASTM F 1043 and F 1083.

Fence fittings shall conform to the requirements of ASTM F 626. Fittings shall be galvanized steel. Wire ties and clips shall be 9-gage.

Gates, gate posts and gate accessories shall conform to the requirements of ASTM F 900. Coating shall be the same as selected for adjoining fence and framework.

Barbed wire shall be 12 1/2 gage and shall conform to the requirements of ASTM A 121, chain link fence grade.

Galvanized and PVC Coated

Chain link fence fabric shall conform to the requirements of ASTM F 668 for Class 2a or 2b, 2-inch mesh, and 9-gauge galvanized steel wire. The fabric shall have a polymer top coating of the color specified in Section 6.

Posts and fence framework shall conform to the requirements of ASTM F 1043 Group 1A, for Heavy Industrial Fence. Coatings shall be a Type A galvanized coating for both internal and external surfaces and covered with a polymer top coating of color as specified in Section 6.

Fence fittings shall conform to the requirements of ASTM F 626. Fittings shall be galvanized steel with a polymer top coating of color as specified in Section 6.

Any damage to the coating shall be repaired in accordance with the manufacturer's recommendations or the damaged fencing material shall be replaced. The Contractor shall provide the Engineer a copy of the manufacturer's recommended repair procedure and materials prior to correcting damaged coatings.

3. INSTALLING FENCE POSTS

Unless otherwise specified, line posts shall be placed at intervals of ten (10) feet measured from center to center of adjacent posts. In determining the post spacing, measurement will be made parallel with the ground surface.

Posts shall be set in concrete backfill in the manner shown on the drawings.

Posts set in the tops of concrete walls shall be grouted into preformed holes to a depth of 12-inches.

All corner posts, end posts, gate posts, and pull posts shall be embedded, braced and trussed as shown on the drawings or in accordance with appropriate industry practice if not otherwise shown or specified.

4. INSTALLING WIRE FABRIC

Fencing fabric shall not be stretched until at least four (4) days after the posts are grouted into walls or seven (7) days after the posts are set in the concrete backfill.

Fencing fabric shall be installed on the side of the posts designated on the drawings.

The fabric shall be stretched taut and securely fastened, by means of tie clips, to the posts at intervals not exceeding 15-inches and to the top rails or tension wires at intervals not exceeding two (2) feet. Care shall be taken to equalize the fabric tension on each side of each post.

Barbed wire shall be installed as shown on the drawings and shall be pulled taut and fastened to each post or arm with the tie wires or metal tie clips.

5. MEASUREMENT AND PAYMENT

Method 1 The length of fence will be measured to the nearest 0.1 foot along the fence, including gates. Payment will be made at the contract unit price for the specified height of fence. Such payment will constitute full compensation for all labor, materials, equipment and all other items necessary and incidental to the completion of the work.

Method 2 The length of fence will be measured to the nearest 0.1 foot along the fence, excluding gate openings. Payment will be made at the contract unit price for the specified height of fence. The number of each size and type of gate installed will be determined. Payment will be made at the contract unit price for that type and size of gate. Such payment will constitute full compensation for all labor, materials, equipment and all other items necessary and incidental to the completion of the work.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed

in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 6 of this specification.

INSTRUCTION FOR USE OF CONSTRUCTION SPECIFICATION 92

FIELD FENCE

1. APPLICABILITY

Construction Specification 92 is applicable to the installation of field fence of the barbed wire, woven wire or wire netting types.

2. MATERIAL SPECIFICATIONS

Material Specification 591 is complementary to Construction Specification 92.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Plan showing the location and extent of fences including location of gates, corners, braces, and end points.
- b. Dimensions of the fence including post spacing, clearance from ground and height of fence.
- c. Details of concrete or other specialty post, if required.
- d. Details of posts and assemblies.
 - (1) Type and type of posts as defined and referenced in Material Specification 591.
 - (2) Line post detail showing height of post, depth of embedment.
 - (3) Details of end panel assembly, pull post assembly, brace panel assembly and corner assembly including types of posts, types of backfill, types and dimensions of braces, gauges of tension wires and details of fastening of tension wires to post.
 - (4) Special anchor requirements for posts at crossings over depressions or waterways.
 - (5) Where fencing is to be placed on a curved alignment, special consideration should be given to providing adequate vertical stability for prevention of pull-over. Consideration should include spacing of end panels, post spacing, type of posts and post depth.
- e. Details of gates. The details listed in b, c, d, and e, may often be shown on a standard drawing developed for use for fencing projects within an agency administrative area.
- f. Type and kind of fencing, as defined in Section 11.
 - (1) For barbed wire fencing, specify the type, gauge of wire, gauge and spacing of barbs and the number of points per barb.

(2) For woven wire fencing, specify the type, style, design number, and tensile strength grade.

(3) For wire netting, specify the type, style, height of netting, size of mesh and gauge of wire, or design number and coating class.

(4) For high tensile strength wire fencing material, specify the strength grade classification.

g. Species of wood posts.

h. Preservative treatment of wood posts and braces, as applicable.

i. Protective coating (painted or zinc-coated) for steel posts and braces.

4. DISCUSSION OF METHODS

a. Section 10, Measurement and Payment

(1) Method 1 is intended for use when gates are simple and are considered to be of field fabricated type.

(2) Method 2 is intended for use when gates must be shop fabricated, available on the market, or when gates must be installed within existing fences.

When specifications are prepared using electronic procedures and all but one method is deleted for use in a contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

92. FIELD FENCE

1. SCOPE

The work shall consist of furnishing and installing field fence, including gates and fittings.

2. MATERIALS

Materials for field fence shall conform to the requirements of Material Specification [591](#). All wooden posts shall be of the same species, when available.

3. SETTING POSTS

Concrete or wood posts shall be set in holes and backfilled with earth except where otherwise specified. Wood posts may be driven when approved by the Engineer. Steel posts shall be driven unless otherwise specified.

Holes for installing fence posts shall be at least six (6) inches larger than the diameter or side dimension of the posts.

Earth backfill around posts shall be thoroughly tamped in layers not thicker than four (4) inches and shall completely fill the posthole up to the ground surface. Concrete backfill around posts shall be rodded into place in layers not thicker than 12-inches and shall completely fill the posthole to the surface of the ground. Backfill, either earth or concrete, shall be crowned-up around posts at the ground surface.

No stress shall be applied to posts set in concrete for a period of not less than 24-hours following the development of a firm set of the concrete.

4. CORNER ASSEMBLY

Unless otherwise specified in Section 11, corner assemblies shall be installed at all points where the fence alignment changes 15 degrees or more.

5. END PANELS

End panels shall be built at gates and fence ends.

6. PULL POST ASSEMBLY

Pull post assembly (bracing within a section of straight fence) shall be installed at the following locations:

- a. In straight fence sections, at intervals not to exceed 660 feet.
- b. At any point where the vertical angle described by two adjacent reaches of wire is upward and exceeds ten (10) degrees (except as provided in Section 11 of this specification).

- c. At the beginning and end of each curved fence section.

7. ATTACHING FENCING TO POSTS

The fencing shall be stretched and attached to posts as follows:

- a. The fencing wire or netting shall be placed on the side of the post opposite the area being protected, except for installation along curved sections.
- b. The fencing wire or netting shall be placed on the outside for installation along curved sections.
- c. The fencing wire or netting shall be fastened to each end post, corner post and pull post by wrapping each horizontal strand around the post and tying it back on itself with not less than three (3) tightly wound wraps.
- d. The fencing wire or netting shall be fastened to wooden line posts by means of steel staples. Woven wire fencing shall be attached at alternate horizontal strands. Each strand of barbed wire shall be attached to each post. Steel staples shall be driven diagonally with the grain of wood and at a slight downward angle and shall not be driven so tightly as to bind the wire against the post.
- e. The fencing wire or netting shall be fastened to steel or concrete line posts with either two turns of 14 gauge galvanized steel or iron wire or in accordance with recommendations provided by the post's manufacturer.
- f. Wire shall be spliced by means of a Western Union splice or by suitable splice sleeves applied with a tool designed for that purpose. The Western Union splice shall have no less than eight (8) wraps of each end about the other. All wraps shall be tightly wound and closely spaced. Splices made with splice sleeves shall have a tensile strength no less than 80 percent of the strength of the wire being spliced.

8. STAYS

Stays shall be attached to the fencing, at the spacing outlined in Section 11 or as shown on the drawings, to ensure maintenance of the proper spacing of the fence wire strands.

9. CROSSINGS AT DEPRESSIONS AND WATERCOURSES

Where fencing is installed parallel to the ground surface, the line posts subject to upward pull shall be anchored.

- a. If the fence wire or netting is installed parallel to the ground surface, the line posts subject to uplift shall be anchored by means of extra embedment or by special anchors as detailed on the drawings.

- b. If the fence wire is installed with the top wire straight and parallel to the ground surface on either side of the depression, extra length posts shall be used to allow normal post embedment. Unless otherwise specified, excess space between the bottom of the fence and the ground shall be closed with extra strands of barbed wire or with netting.

10. MEASUREMENT AND PAYMENT

Method 1 The length of each type and kind of fence will be measured to the nearest foot along the profile of the fence, including gate openings. Payment for each type and kind of fence will be made at the contract unit price for that type and kind of fence. Such payment will constitute full compensation for completion of the work, including fabricating and installing gates.

Method 2 The length of each type and kind of fence will be measured to the nearest foot along the profile of the fence, excluding gate openings. Payment will be made at the contract unit price for the specified height of fence. The number of each size and type of gate installed will be determined. Payment will be made at the contract unit price for that type and size of gate. Such payment will constitute full compensation for all labor, materials, equipment and all other items necessary and incidental to the completion of the work.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 11 of this specification.

IDENTIFICATION MARKER OR PLAQUES

1. APPLICABILITY

The construction specification is applicable to the installation of identification markers or plaques to the works of improvement.

2. MATERIAL SPECIFICATIONS

There are no material specifications complementary to this specification. Any specific material requirements must be indicated in the specifications or on the drawings.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. Complete detail drawings for each type, kind, and size of marker or plaque, including material requirements.
- b. The style of letters and height of each line.
- c. A carefully worded exhibit showing the exact arrangement of words.
- d. The physical description for the installation location for each type, size of marker or plaque to be installed. Location selected should consider the audience intended and the potential for vandalism.
- e. Type of required monument or type of structure to which marker or plaque will be mounted.
- f. For markers signifying buried structures, state and/or local government regulations for sign specifications may apply. Ensure that project sign message and state and/or local government rules do not conflict.

4. DISCUSSION OF METHODS

a. Section 5, Measurement and Payment

(1) Method 1 is intended for use when various, sizes and types of markers or plaques are to be installed.

(2) Method 2 is intended for use when a single marker or plaque is to be installed or multiple number of markers are to be installed and they are of similar type and size.

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

93. IDENTIFICATION MARKERS OR PLAQUES

1. SCOPE

The work shall consist of furnishing and installing identification markers or plaques at the designated locations.

2. MATERIALS

The markers or plaques shall be constructed of the specified materials, and shall meet all requirements for lettering, painting, finishing, and related items as shown on the drawings or as specified in Section 6 of this specification.

3. CONSTRUCTION METHODS

The markers or plaques shall be installed at location(s) as shown on the drawings and in the manner or condition specified in Section 6.

4. MONUMENTS

Unless otherwise specified, the markers or plaques shall be mounted on concrete monuments, on existing structures, or on structures proposed for installation under this contract.

5. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established in the contract, payment for each type, kind, and size of marker or plaque complete in place, will be made at the contract unit price for that type, kind, and size. Such payment will constitute full compensation for all labor, equipment, tools, and all other items necessary and incidental to the completion of the work.

Method 2 For items of work for which specific lump sum prices are established in the contract, payment for identification markers or plaques will be made at the contract lump sum price. Such payment will constitute full compensation for all labor, equipment, tools, and all other items necessary and incidental to the completion of the work.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 6 of this specification.

CONTRACTOR QUALITY CONTROL

1. APPLICABILITY

Construction Specification 94 is applicable to contracts that require the Contractor to provide quality control (QC), material testing and verification of material quality prior to use.

2. MATERIAL SPECIFICATIONS

There are no material specifications complementary to Construction Specification 94. Any material requirements are to be specified in Section 10 (see 3.b. below).

3. ITEMS TO BE INCLUDED IN THE CONTRACT SPECIFICATION AND DRAWINGS

- a. Develop specific requirements for the quality control testing that the Contractor is to provide. Establish, as appropriate for the method selected, the types of material the Contractor will be required to test, types of representative tests required, frequency of tests and other site specific related details.
- b. Provide details on the required intensity of Contractor's quality control inspection efforts with emphasis on the site specific aspects of the work, equipment and materials to be used. Specify, as appropriate for the method selected, the documentation required for: verification of foundations and cutoff trench excavations, subgrade for fills, placement of reinforcement and forming prior to ordering concrete, equipment operational tests and available equipment backups, safety measures specified, etc. Prescribe specific requirements regarding:
 - (1) Reliance on Contractor for initial or benchmark testing, production testing and testing to adjust to changes in materials or methods.
 - (2) Standards to be used as reference for quality control testing and field inspections of materials, methods and procedures.
 - (3) Special testing or inspection procedures that need to be included in the quality control system.
- c. Contract specific qualifications or requirements for professional registration or certification of QC personnel if necessary to meet federal, state or local statutes or job requirements.
- d. Specify the required approvals by the Contracting Officer, not covered in the basic specification for items such as: personnel qualifications, equipment condition, format of record keeping and documentation, etc.
- e. Describe the cooperation and communication aspects for the quality control and quality assurance (QA) activities.

4. DISCUSSION OF METHODS

a. Section 3, Quality Control System and Section 4, Quality Control Personnel

- (1) Method 1 is for use with the smaller or less complex work where the Contractor's staff is expected to understand and be qualified to perform routine quality control. The Contractor must develop an effective quality control system. The Contractor and Contracting Officer will meet and reach agreement on the system. Specify in Section 10 if the Contracting Officer will document by correspondence to the Contractor the understanding reached concerning the quality control system. When the project foreman can also function as the Contractor's quality control manager, so state in Section 10.
- (2) Method 2 is for use with large or complex work where the Contractor is required to have qualified quality control testing and inspection personnel on their staff or will subcontract for these services and provide NRCS with a written quality control plan and regularly submit quality control documentation.

Selection of either Method 1 or Method 2 in Sections 3 and 4 must be uniformly made within the specification for each contract.

b. Section 9, Payment

- (1) Method 1 is for use for larger more complex projects where uniformity in QC activities may not exist.
- (2) Method 2 is for smaller, simpler projects. The use of Method 2 is encouraged when fair and equitable treatment will occur.

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete "All Methods The following provisions apply to all methods of payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

94. CONTRACTOR QUALITY CONTROL

1. SCOPE

The work consists of developing, implementing, and maintaining a quality control system to ensure that the specified quality is achieved for all materials and work performed.

2. EQUIPMENT AND MATERIALS

Equipment and materials used for quality control shall be of the quality and condition required to meet the test specifications cited in the contract. Testing equipment shall be properly adjusted and calibrated at the start of operations and the calibration maintained at the frequency specified. Records of equipment calibration tests shall be available to the Engineer at all times. Equipment shall be operated and maintained by qualified operators, as prescribed in the manufacturer's operating instructions, the references specified and as specified in Section 10 of this specification. All equipment and materials used in performing quality control testing shall be as prescribed by the test standards referenced in the contract or in Section 10.

All equipment and materials shall be handled and operated in a safe and proper manner and shall comply with all applicable regulations pertaining to their use, operation, handling, storage, and transportation.

3. QUALITY CONTROL SYSTEM

Method 1 The Contractor shall develop, implement and maintain a system of quality control to provide the specified material testing and verification of material quality before use. The system activities shall include procedures to verify adequacy of completed work, initiate corrective action to be taken and document the final results. The identification of the quality control personnel and their duties and authorities shall be submitted to the Contracting Officer in writing within 15 calendar days after notice of award.

Method 2 The Contractor shall develop, implement and maintain a system adequate to achieve the specified quality of all work performed, material incorporated and equipment furnished prior to use. The system established shall be documented in a written plan developed by the Contractor and approved by the Contracting Officer. The system activities shall include the material testing and inspection needed to verify the adequacy of completed work and procedures to be followed when corrective action is required. Daily records to substantiate the conduct of the system shall be maintained by the Contractor. The quality control plan shall cover all aspects of quality control and shall address, as a minimum, all specified testing and inspection requirements. The plan provided shall be consistent with the planned performance in the Contractor's approved construction schedule. The plan shall identify the Contractor's on-site quality control manager and provide an organizational listing of all quality control personnel and their specific duties. The

written plan shall be submitted to the Contracting Officer within 15 calendar days after notice of award. The Contractor shall not proceed with any construction activity which requires inspection until the written plan is approved by the Contracting Officer.

All Methods The quality control system shall include, but not be limited to, a rigorous examination of construction materials, processes and operation, including testing of materials and examination of manufacturer's certifications as required, to verify that work meets contract requirements and is performed in a competent manner.

4. QUALITY CONTROL PERSONNEL

Method 1 Quality control activities shall be accomplished by competent personnel. A competent person is: one who is experienced and capable of identifying, evaluating, and documenting that materials and processes being used will result in work that complies with the contract; and, who has authority to take prompt action to remove, replace, or correct such work or products not in compliance. Off-site testing laboratories shall be certified or inspected by a nationally recognized entity. The Contractor shall submit to the Contracting Officer, for approval, the names, qualifications, authorities, certifications, and availability of the competent personnel who will perform the quality control activities.

Method 2 Quality control activities shall be accomplished by competent personnel who are separate and apart from line supervision and who report directly to management. A competent person is: one who is experienced and capable of identifying, evaluating, and documenting that materials and processes being used will result in work that complies with the contract; and, who has authorization to take prompt action to remove, replace, or correct such work or products not in compliance. Off-site testing laboratories shall be certified or inspected by a nationally recognized entity. The Contractor shall submit to the Contracting Officer, for approval, the names, qualifications, authorities, certifications, and availability of the competent personnel who will perform the quality control activities.

5. POST-AWARD CONFERENCE

The Contractor shall meet with the Contracting Officer prior to the beginning of any work and discuss the Contractor's quality control system. The Contracting Officer and the Contractor shall develop a mutual understanding regarding the quality control system.

6. RECORDS

The Contractor's quality control records shall document both acceptable and deficient features of the work and corrective actions taken. All records shall be on forms approved by the Contracting Officer; legible; and dated and signed by the competent person creating the record.

Unless otherwise specified in Section 10 of this specification, records shall include:

- a. Documentation of shop drawings including date submitted to and date approved by the Contracting Officer, results of examinations, any need for changes or modifications, manufacturer's recommendations and certifications, if any, and signature of the authorized examiner.
- b. Documentation of material delivered including quantity, storage location, and results of quality control examinations and tests.
- c. Type, number, date, time, and name of individual performing of quality control activities.
- d. The material or item inspected and tested, the location and extent of such material or item, and a description of conditions observed and test results obtained during the quality control activity.
- e. The determination that the material or item met the contract provisions and documentation that the Engineer was notified.
- f. For deficient work the nature of the defects, specifications not met, etc., corrective action taken and results of quality control activities on the corrected material or item.

7. REPORTING RESULTS

The results of Contractor quality control inspections and tests shall be communicated to the Engineer immediately upon completion of the inspection or test. Unless otherwise specified in Section 10, the original plus one copy of all records, inspections, tests performed and material testing reports shall be submitted to the Engineer within one working day of completion. The original plus one copy of documentation of materials delivered shall be submitted to the Engineer before the material is used.

8. ACCESS

The Contracting Officer and the Engineer shall be given free access to all testing equipment, facilities, sites, and related records for the duration of the contract.

9. PAYMENT

Method 1 For items of work for which lump sum prices are established in the contract, payment will be made as the work proceeds, after presentation by the Contractor of invoices showing related costs and evidence of charges by suppliers, subcontractors, and others for furnishing supplies and work performed. If the total of such payments is less than the lump sum contract price for this item, the remaining balance will be included in the final contract payment. Payment of the lump sum contract price will constitute full compensation for completion of the work.

Payment is not made under this item for the purchase cost of materials and equipment having a residual value.

Method 2 For items of work for which lump sum prices are established in the contract, payment will be prorated and paid in equal amounts on each monthly estimate. The number of months used for prorating shall be the number estimated to complete the work. The final month's prorate amount will be made with the final payment. Payment as described above will constitute full compensation for completion of the work.

Payment will not be made under this item for the purchase cost of materials and equipment having a residual value.

All Methods The following provisions apply to all methods of payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 10.

GEOTEXTILE

1. APPLICABILITY

This specification is applicable for the installation of both woven and nonwoven geotextiles used for purposes of slope protection, subsurface drains and stabilization of soils.

2. MATERIAL SPECIFICATIONS

Material Specification [592](#) is complementary to Construction Specification 95.

3. ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS

- a. The purpose or use of the geotextile (i.e., slope protection) and the selection of Class I, II, III or IV, as appropriate, woven or nonwoven, (See Design Note 24).
- b. The range of apparent opening size (AOS) for woven geotextiles. Any increase or change from those parameters shown in Tables 1 and 2 that are desired and based on specific design data.
- c. When specified, size and configuration of panels for payment (e.g., Method 2). Note: A panel represents pieces from a roll that have been seamed together to create the specified size and shape.
- d. Details of panel joining and splicing, i.e., seaming, overlap or folding (Method 1 or Method 2 in Section 5).
- e. The required roll width, when necessary.
- f. Details of panel placement, orientation and anchorage, when necessary. Perimeter and toe anchorage details, as necessary. When the use of pins is acceptable as temporary anchorage, so specify.
- g. Requirements of cushioning or bedding materials used to cover the geotextile to protect against damage during placement of surface material, such as rock riprap.
- h. Special installation requirements.
- i. Ultraviolet exposure requirements for conditions where the potential exposure is considered severe (use 500 hours). The 150 hours requirement listed in Tables 1 and 2 are recommended for normal exposure conditions.
- j. In Section 6 for measurement when Method 1 or 2 is selected, note the method of measurement being horizontal or slope measurement in determining surface area of the geotextile for payment purposes.

4. DISCUSSION OF METHODS

a. Section 5, Placement.

- (1) Method 1 is intended to be used when the primary use of the geotextile is to function as a filter and holes or "holidays" from anchoring pins might compromise the integrity of the installation.
- (2) Method 2 is intended to be used when the primary use of the geotextile is to function as a bedding and as a separator of materials. Seepage may be present but the potential for piping in the base soil materials is not a concern.

May also need to specify whether a., b., or c applies.

b. Section 6, Measurement and Payment.

- (1) Method 1 is intended for use when the geotextile is measured for payment based on the total surface area covered. The additional lap material needed for joining is not measured for payment.
- (2) Method 2 is intended for use when the geotextile is measured for payment based on the roll width and length used to cover the area. The measurement includes that amount needed for overlap and joining panels.
- (3) Method 3 is intended for use when the quantity will not be measured for payment and there is not likely to be any change in quantity.

When specifications are prepared using electronic procedures and all but one method are deleted for use in the contract specification, delete, "All Methods The following provisions apply to all methods of measurement and payment." and left justify the remaining text.

CONSTRUCTION SPECIFICATION

95. GEOTEXTILE

1. SCOPE

This work shall consist of furnishing all materials, equipment, and labor necessary for the installation of geotextiles.

2. QUALITY

Geotextiles shall conform to the requirements of Material Specification 592 and this specification.

3. STORAGE

Prior to use, the geotextile shall be stored in a clean dry location, out of direct sunlight, not subject to extremes of either hot or cold temperatures, and with the manufacturer's protective cover undisturbed. Receiving, storage, and handling at the job site shall be in accordance with the requirements listed in ASTM D 4873.

4. SURFACE PREPARATION

The surface on which the geotextile is to be placed shall be graded to the neat lines and grades as shown on the drawings. The surface shall be reasonably smooth and free of loose rock and clods, holes, depressions, projections, muddy conditions and standing or flowing water (unless otherwise specified in Section 7 of this specification).

5. PLACEMENT

Prior to placement of the geotextile, the soil surface will be reviewed for quality assurance of the design and construction. The geotextile shall be placed on the approved prepared surface at the locations and in accordance with the details shown on the drawings and specified in Section 7 of this specification. The geotextile shall be unrolled along the placement area and loosely laid, without stretching, in such a manner that it will conform to the surface irregularities when material or gabions are placed on or against it. The geotextile may be folded and overlapped to permit proper placement in designated area(s).

Method 1 The geotextile shall be joined by machine sewing using thread material meeting the chemical requirements for the geotextile fibers or yarn. The sewn overlap shall be six (6) inches and the sewing shall consist of two (2) parallel stitched rows at a spacing of approximately one (1) inch and shall not cross (except for any required re-stitching). The stitching shall be a lock-type stitch. Each row of stitching shall be located a minimum of two (2) inches from the geotextile edge. The seam type and sewing machine to be used shall produce a seam strength, in the specified geotextile, that provides a minimum of 90-percent of the tensile strength in the weakest principal direction of the geotextile being used, when tested in accordance with ASTM D 4884. The seams may be factory or field sewn.

The geotextile shall be temporarily secured during placement of overlying materials to prevent slippage, folding, wrinkling, or other displacement of the geotextile. Unless otherwise specified, methods of securing shall not cause punctures, tears or other openings to be formed in the geotextile.

Method 2 The geotextile shall be joined by overlapping a minimum of 18 inches (unless otherwise specified), and secured against the underlying foundation material. Securing pins, approved and provided by the geotextile manufacturer, shall be placed along the edge of the panel or roll material to adequately hold it in place during installation. Pins shall be steel or fiberglass formed as a “U”, “L”, or “T” shape or contain “ears” to prevent total penetration through the geotextile. Steel washers shall be provided on all but the “U” shaped pins. The upstream or up-slope geotextile shall overlap the abutting down-slope geotextile. At vertical laps, securing pins shall be inserted through the bottom layers along a line through approximately the mid-point of the overlap. At horizontal laps and across slope laps, securing shall be inserted through the bottom layer only. Securing pins shall be placed along a line approximately two (2) inches in from the edge of the placed geotextile at intervals not to exceed 12 feet unless otherwise specified. Additional pins shall be installed as necessary and where appropriate, to prevent any undue slippage or movement of the geotextile. The use of securing pins will be held to the minimum necessary. Pins are to remain in-place unless otherwise specified.

Should the geotextile be torn or punctured, or the overlaps or sewn joint disturbed, as evidenced by visible geotextile damage, subgrade pumping, intrusion, or grade distortion, the backfill around the damaged or displaced area shall be removed and restored to the original approved condition. The repair shall consist of a patch of the same type of geotextile being used and overlaying the existing geotextile. When the geotextile seams are required to be sewn, the overlay patch shall extend a minimum of one (1) foot beyond the edge of any damaged area and joined by sewing as required for the original geotextile except that the sewing shall be a minimum of six (6) inches from the edge of the damaged geotextile. Geotextile panels joined by overlap shall have the patch extend a minimum of two (2) feet from the edge of any damaged area.

Geotextile shall be placed in accordance with the following applicable specification according to the use indicated in Section 7:

- a. Slope Protection The geotextile shall not be placed until it can be anchored and protected with the specified covering within 48 hours or protected from exposure to ultraviolet light. In no case shall material be dropped on uncovered geotextile from a height greater than three (3) feet.
- b. Subsurface Drains The geotextile shall not be placed until drainfill or other material can be used to provide cover within the same working day. Drainfill material shall be placed in a manner that prevents damage to the geotextile. In no case shall material be dropped on uncovered geotextile from a height greater than five (5) feet.

- c. Road Stabilization The geotextile shall be unrolled in a direction parallel to the roadway centerline in a loose manner permitting conformation to the surface irregularities when the roadway fill material is placed on its surface. In no case shall material be dropped on uncovered geotextile from a height greater than five (5) feet. Unless otherwise specified, the minimum overlap of geotextile panels joined without sewing shall be 24 inches. The geotextile may be temporarily secured with pins recommended or provided by the manufacturer, but they shall be removed prior to placement of the permanent covering material.

6. MEASUREMENT AND PAYMENT

Method 1 For items of work for which specific unit prices are established in the contract, the quantity of geotextile for each type placed within the specified limits will be determined to the nearest specified unit by measurements of the covered surfaces only, disregarding that required for anchorage, seams, and overlaps. Payment will be made at the contract unit price. Such payment will constitute full compensation for the completion of the work.

Method 2 For items of work for which specific unit prices are established in the contract, the quantity of geotextile for each type placed with the specified limits will be determined to the nearest specified unit by computing the area of the actual roll size, or partial roll size installed. The computed area will include the amount required for overlap, seams, and anchorage as specified. Payment will be made at the contract unit price. Such payment will constitute full compensation for the completion of the work.

Method 3 For items of work for which specific lump sum prices are established in the contract, the quantity of geotextile will not be measured for payment. Payment for geotextiles will be made at the contract lump sum price and will constitute full compensation for the completion of the work.

All Methods The following provisions apply to all methods of measurement and payment. Compensation for any item of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 7 of this specification.

FIELD OFFICE

1. **APPLICABILITY**

Construction Specification 96 is applicable when an on-site project field office with the basic facilities for material testing and construction office needs is to be furnished by the Contractor.

2. **MATERIAL SPECIFICATIONS**

There are no material specifications complementary to Construction Specification 96.

3. **ITEMS TO BE INCLUDED IN CONTRACT SPECIFICATIONS AND DRAWINGS**

- a. Type of field office; identify Type A, B, or C from Table I. If other equipment than that specified is required or is not necessary, supplement or amend Table I in Section 5 of this specification to provide appropriate requirements.
- b. Identify any exception, deletion, or special needs in the equipment, materials or furnishings, such as blinds, lighting, testing equipment (microwave oven, etc.), toilet facilities, typewriter (electric or manual), secure storage for nuclear equipment, computer (minimum features need to be identified), copy machine, FAX machine, telephone with answering equipment, etc. It should be determined if NRCS or Sponsors are to furnish any required items or if they should be included in the contract for the Contractor to provide.
- c. Include the responsibility for providing service during the construction period; such as delivery of bottled water, sanitary facility service, cleaning service, snow removal, maintenance of the field office equipment, electric service, etc. Include any requirements for inspections by utilities or government authorities, such as electrical safety inspection, fire department, etc.
- d. Show on the drawings the approximate location where facilities are to be placed. When known, show the location of the utility services (electricity, natural gas, telephone, water, sewer, etc.) available.

4. **DISCUSSION OF METHODS**

No Methods are outlined in the Specification.

CONSTRUCTION SPECIFICATION

96. FIELD OFFICE

1. SCOPE

This work shall consist of furnishing and maintaining a field office for the exclusive use of the Engineer and other employees of the owner.

2. LOGISTICS

The approximate location of the office shall be as shown on the drawings. Office space provided under this contract item shall be separated from any space used by the Contractor for other purposes.

The field office and appurtenances shall be set up, equipped, and made ready for use within twenty (20) days of the receipt of the written Notice to Proceed, unless otherwise specified in Section 5. The field office and appurtenances shall remain the property of, and shall be maintained in good condition and appearance by the Contractor until completion of the contract work.

When a mobile field office facility is furnished, it shall be leveled, blocked, and anchored in accordance with Standard A 225.1 of *Manufactured Home Installations, 1987 of the National Conference of States on Building Codes and Standards, Inc.* or the requirements of the local government that has jurisdiction.

The Contractor shall install, provide and maintain all utilities, except telephone service, as outlined in Section 5. Contractor shall provide access to the telephone company and authorization for the installation of telephone service for the use of NRCS and their agents. Utility service maintenance may include: heating fuel, electricity, water, sewer, etc. Contractor shall provide a sanitary facility (toilet) in accordance with the minimum OSHA Safety and Health Requirements for use by NRCS and their agents (See Table I footnote **).

The Contractor shall provide and maintain a reasonable access road to the field office location together with parking for a minimum of four (4) vehicles in the proximity of the field office site.

Upon completion and acceptance of the project work the Contractor shall remove the field office from the project site, and unless otherwise directed, shall restore all areas affected by the field office installation, including the entrance road and parking areas, to a condition equal to or better than existed prior to installation of the field office.

3. MATERIALS AND FURNISHINGS

The Contractor shall furnish all materials and furnishings as set forth below:

- a. The Contractor shall provide the type of field office as specified in Section 5 of this specification.

b. The field office shall include or possess as a minimum, the features shown below and as specified in Table I for the Office Type specified.

- (1) Be provided with all items in a clean, usable condition.
- (2) Be structurally sound, entirely enclosed, secure, and waterproof.
- (3) Have a ceiling height of not less than seven (7) feet.
- (4) Be attractively painted on the outside with a finished interior.
- (5) Be provided with two (2) exterior doors, except Type C Office shall have one door, that shall be equipped with dead-bolt type cylinder locks, including four (4) keys for each lock. Exterior lock and hasps, or equivalent, shall also be provided for each door.
- (6) Windows shall be equipped with screens and with provisions for opening and closing. Latches or other approved locking provisions to secure the windows shall be provided.
- (7) Window blinds shall be available and provided for all windows.
- (8) Be provided with adequate artificial lighting to provide an average of fifty (50) candlepower to all work areas within the office. Overhead lamps for each desk and drafting table shall be provided. Electric service shall be continuous for the period the field office is being utilized to service this contract. Electric lights and power service shall be supplied with at least four (4) grounded duplex convenience outlets installed in each room.
- (9) Be provided with an approved heating system capable of maintaining a temperature of at least 70° F throughout the office during the periods of cold weather that can be expected to occur during the construction period.
- (10) Be provided with an approved air conditioner(s) with a minimum capacity of 15,000 BTUs for each office room.
- (11) Be provided with an electric or gas hot water heater with a five (5) gallon minimum capacity.

c. The field office shall be furnished with the following listed minimum equipment in good condition and as specified in Table I.

- (1) Desk(s) shall have a minimum of two (2) drawers on each side and have minimum surface dimensions of 30 inches by 60 inches. A standard office chair with arm rests and casters shall be provided with each desk.

- (2) A slant-top adjustable height drafting table with the approximate dimensions 36-inches wide by 60-inches long and 36-inches height with an adjustable height drafting stool.
- (3) Work table with the approximate dimensions of 30-inches wide by 60-inches long and 30-inches high, a portable meeting table of approximate dimensions 36-inches wide by 72 inches long and 30-inches high, and a minimum of six folding or stacking office chairs.
- (4) Closets with a minimum clear height of seven (7) feet and approximately 24-inches by 30-inches equipped with two adjustable and removable shelves.
- (5) Bookcases or built-in shelving equivalent to five-4 feet long shelves, each ten (10) inches wide and twelve (12) inches in height, suitably located to reflect an office environment.
- (6) One (1) two-burner propane or natural gas stove or electric grill that can accommodate two 12-inch diameter pans. Heating capacity shall be adequate to remove soil moisture to meet the requirements of the ASTM quick dry method.
- (7) Underwriters Laboratory approved wall mounted Fire Extinguisher with a minimum rating of 10 ABC.
- (8) Minimum of one (1) 16-unit first aid kit, approved by or certified by the American Red Cross or equivalent.
- (9) Four (4) drawer locking fireproof metal file cabinet with two (2) keys provided.
- (10) Electrical refrigerated cold water drinking equipment supplied with potable drinking water and disposable cups for the duration of the contract.
- (11) Racks for hanging drawings, together with holders or clamps, to accommodate 24" by 36" maximum size sheets.
- (12) Each field office entrance will be provided with non-skid steps and landing platform with safety handrail.
- (13) One (1) electric typewriter.
- (14) One (1) inside and usable sanitary facility (flush type) located within a private room.
- (15) One (1) utility sink approximately 24-inches by 24-inches equipped with hot and cold running water.

- (16) One laboratory oven with two adjustable shelves, thermostatically controlled, minimum 800 watts with minimum inside dimensions of 12" by 10" by 10", capable of maintaining a constant temperature in the range of 100° C to 110° C, suitable for drying samples in accordance with ASTM Testing Procedures. The oven shall operate on 120 volt, AC current.
 - (17) One microwave oven with specifications as listed in footnote (****) to Table I
- d. Prior to mobilizing and setting up the field office, the Contractor shall prepare and submit detailed plans of the office to the Engineer.
 - e. The Contractor shall provide access to the Engineer for visual verification that the office and equipment meet contract requirements prior to mobilizing the field office to the work site.

4. PAYMENT

This item will not be measured but will be paid at the contract lump sum price established for this bid item in the contract, including mobilization and demobilization.

The following progress payment schedule will apply unless other provisions are outlined in Section 5 of this specification: Basis of payment will be forty (40) percent of the lump sum price bid will be payable for the first monthly progress payment following satisfactory delivery and set-up complete with full service installed. Twenty (20) percent will be retained to cover the removal of service and demobilization following completion of the work and will be included in the final payment. The forty (40) percent remaining will be prorated over the balance of the contract in accordance with the planned construction schedule. Payment as described herein will be full compensation for all labor, materials, supplies, equipment, rental fees, utility charges (excluding telephone service charges), and incidentals required to provide, equip, maintain, insure, and clean-up the site following demobilization of the field office unit.

TABLE I

Equipment	Field Office Type		
	Type A	Type B	Type C
Floor space (sq. ft.)	480 (2 rooms)	360 (2 rooms)	120 (1)
Window Space (sq. ft.)	66	50	30
Air Conditioning	Yes	Yes	Yes
Desk and Chair	3	2	1
Rack for Drawings	1	1	-
Work Tables	2	1	1
Meeting Table	1	1	-
Drafting Table and Stool	2	1	-
4-drawer file (D label) metal file cabinet	2	1	-
Folding/Office Chairs	10	8	4
Electric water cooler	1	1	1
Inside sanitary facility	1* *	1* *	1* *
Oven, electric	1	1	-
Oven, Microwave	1* * * *	1* * * *	-
Cupboards, closets, etc.	*	*	*
2-burner stove	1	1	-
Fire Extinguisher	1	1	1
First Aid Kit (16 unit)	1	1	1
Utility Sink	1	1	-
Window Blinds	Yes	Yes	No
Electrical Service	Yes	Yes	* * *
Desk and Table Lamps	Yes	Yes	No

Footnotes:

- * Reasonable number for the size of the office.
- * * Exterior self-contained sanitary facilities within 100 feet of the office with maintenance service is an option.
- * * * A generator to provide electric service for heating, lighting, and calculators is sufficient. Contractor is responsible for maintenance, fuel supplies, and service.
- * * * * A variable power microwave oven with minimum inside dimensions of 12" X 10" X 10". The maximum power setting on the microwave oven shall operate at approximately 650 watts. The microwave oven shall have at least one power setting that operates at between 300 and 400 watts.

INSTRUCTIONS FOR USE OF CONSTRUCTION SPECIFICATION 97

HDPE AND LLDPE LINER

1. APPLICABILITY

Construction Specification 97 is applicable to the placement of HDPE and LLDPE geosynthetic liners in liquid containment systems to control seepage.

2. MATERIAL SPECIFICATIONS

Material Specification [594, HDPE and LLDPE Flexible Membrane Liner](#), complements Construction Specification 97.

3. INCLUDED ITEMS

Items to be included in the contract drawings and specifications follow:

- a. The type of liner material being used either HDPE or LLDPE and the required thickness.
- b. Details of panel placement, orientation, and anchorage.
- c. Requirements of any cushioning material to be used and the material references for the same.
- d. Requirements for subgrade compaction.
- e. Requirements for under drains and the associated materials.
- f. Details for gas vents and their locations.
- g. Details for any loading, unloading, or cleanout ramps; including batten strips or other means of fastening.
- h. Details for pipe outlets and boots or appurtenances to fit the liner to the outlet.
- i. Details for fences, ladders, or other safety features.
- j. Any special instructions related to the materials or the installation.

CONSTRUCTION SPECIFICATION

97. HDPE AND LLDPE LINER

1. SCOPE

The work shall consist of furnishing and installing an HDPE or LLDPE liner and the necessary mechanical attachments as shown in the drawings or as specified herein.

2. MATERIAL

The liner, welding rod, gaskets, metal battens, clamps, embed channel, and sealant shall conform to the requirements of Material Specification 594, the applicable provisions in this specification, and those shown on the drawings. Subgrade soils and their surface conditions shall conform to the requirements in this specification and as shown in the drawings.

Cover soils, if applicable, shall conform to this specification and as shown on the drawings.

3. SHIPPING AND STORAGE

Liner rolls shall be shipped to the job site in a manner not to damage the rolls. The rolls shall be stored and protected from puncture, dirt, grease, excessive heat, or other damage. They shall be stored on a prepared smooth surface (not wooden pallets) and shall be stacked no more than two rolls high.

4. SUBGRADE PREPARATION

Subgrade soil shall be compacted to provide a firm, unyielding foundation for the liner. All surfaces shall be smooth, free of foreign and organic material, rocks larger than 3/8 inch, any angular rocks, and any sharp objects. Standing water or excessive moisture shall not be allowed.

5. ANCHOR TRENCH

The anchor trench shall provide permanent anchoring for the liner and shall be in accordance with the drawings. The trench shall be excavated according to a daily schedule for liner installation. It shall be backfilled incrementally as needed. Backfill soil shall be compacted by rolling with rubber-tired equipment or a manually directed power tamper to provide a stable anchor trench for the liner.

6. LINER PLACEMENT

Liner rolls shall be deployed using a spreader bar assembly attached to a front-end loader bucket or by other methods approved by the liner manufacturer. The liner shall be placed in the general direction of maximum slope. All of the placed liner shall be adequately ballasted by sandbags to protect it from wind uplift forces. The liner shall be placed on a daily basis and seamed and secured by the end of the workday. No construction equipment shall be allowed directly on the liner except for light ATVs and generators to power the seaming machines.

The liner shall not be placed during fog, precipitation, in the presence of excessive winds, or in temperatures less than 50 degrees Fahrenheit. The liner shall be loosely laid over the foundation with sufficient slack (about 2 percent) to accommodate thermal expansion and contraction encountered during construction. Each panel shall be laid out and positioned to minimize the number and length of the geomembrane field joints and to be consistent with accepted installation practice. The methods used to place panels shall minimize wrinkles especially along field seams. When necessary, a geosynthetic rub sheet will be used under the membrane to prevent damage when dragging or moving the panels.

7. SEAMING

The primary method of seaming shall be hot shoe fusion welding. Fillet extrusion welding shall be used for repairs, T-seams, and detail work. Before fusion welding or extrusion welding, all areas that are to become seam interfaces shall be cleaned of dust and dirt. Seam joining shall not take place unless the sheet is dry and shall not be attempted when the ambient sheet temperature is below 45 degrees Fahrenheit or above 90 degrees Fahrenheit.

Hot shoe welding—Hot shoe welding shall be accomplished by a double-wedge fusion welder that produces a double track weld. All accessories shall be approved by the liner manufacturer. To produce acceptable seams for the site-specific condition, the welder shall be calibrated at the beginning of each seaming period. Seaming procedures shall be in accordance with liner manufacturer specifications.

Fillet extrusion welding—Extrusion welding equipment and accessories shall be approved by liner manufacturer. To produce acceptable seams for the site-specific condition, the extrusion welder shall be calibrated once per day at the beginning of each seaming period. Seaming procedures shall be in accordance with liner manufacturer specifications.

Seam overlap—Liner panels shall have a minimum overlap of 4 inches for hot shoe welding and 3 inches for extrusion welding. Upslope panels shall overlap downslope to provide a shingle effect for drainage.

Seaming equipment and accessories:

- Hot shoe welder, 110 or 220 volts
- Extrusion welder, 220 volts
- Grinder, 10,000 rpm, 4.5-inch side grinder with 80-grit discs
- Generator, 6.5 kW, 110/220 volt output
- Power cord, OSHA approved cords and twist-type plugs and connections
- Vacuum box test equipment, approved by the liner manufacturer

- Air pressure test equipment, approved by the liner manufacturer
- Tensiometer, capable of performing quantitative shear and peel tests

8. SEAM TESTING

Seams shall be tested under field conditions at the beginning of each seaming period and once in the morning and once in the afternoon. Three specimens shall be tested by a tensiometer in shear and peel modes. Test seams shall meet the requirements of Material Specification 594. Each specimen shall be 1 inch wide with the grip separation rate of 2 inches per minute. All peel tests shall result in film tear bond (FTB) value. The FTB is defined as a failure of one of the bonded sheets before complete separation in the bonded area.

Nondestructive seam testing—Air pressure tests shall be performed on all double-wedge fusion seams. The air pressure test equipment and procedures shall conform to this specification and the liner manufacturer's specifications. Seal both ends of the seam to be tested. Insert the pressure needle into the seam's air channel. Pressurize the air channel through the needle to 25 to 30 pounds per square inch.

Monitor any pressure drops for 5 minutes. A loss of pressure in excess of 4 pounds per square inch or a continuous loss of pressure is an indication of a leak. Terminate the test by relieving the pressure from the opposing end of the seam. The pressure shall immediately drop to zero upon opening the opposing end of the seam. If this does not occur, the seam channel shall be checked for obstructions and retested. All defects shall be marked for repair.

Vacuum box tests shall be performed on all extrusion welds. The vacuum box equipment and test procedure shall conform to this specification and the liner manufacturer's specifications. Apply soapy water solution to the seam area to be tested. The vacuum box, equipped with a transparent viewing window, shall be centered over the seam area and a vacuum of 3 pounds per square inch shall be drawn. The seam area shall be visually monitored for any soap bubbles for 15 seconds. Seam testing shall continue by overlapping a minimum of 3 inches between each test interval. All defects shall be marked for repair.

Destructive seam testing—If required, seam samples shall be cut at no more than one sample per 500 feet of weld for destructive seam testing. All destructive seam samples shall be tested by a tensiometer in shear and peel modes to verify seams meet the requirements of Material Specification 594.

9. REPAIRS

All defective liner areas and bad seams shall be repaired and tested before the installation is completed.

Tears, punctures, material defects—All tears, punctures, and material defects in liner shall be repaired by installing a patch over the defective area. Surfaces of the liner to

be patched shall be cleaned before the repair. To ensure proper bonding of the extrusion weld, edges of the patch material and the adjacent liner shall be properly abraded by a light grinding. This operation shall be done no more than 15 minutes before the welding operation. The abrasion shall remove no more than 10 percent of the material thickness. All patches shall be of the same liner material and extend a minimum of 6 inches beyond the edges of the defect area. All patches shall have rounded corners and shall be extrusion welded to the liner. Alternatively, a bead of extrudate shall be placed over all holes that are less than 0.25 inch in diameter.

Seam repair—All failed seams shall be repaired by installing a cap strip over the entire length of failed seam. The cap strip shall be of the same liner material and shall extend the failed seam a minimum of 6 inches in all directions. Alternatively, the seam along the upper flap can be extrusion welded to the liner along the entire length of the failed seam.

10. MECHANICAL ATTACHMENTS

The liner shall be mechanically attached to pipe, concrete, or steel structure as shown in the drawings and according to the liner manufacturer's specification.

Pipe boots—Pipe boots shall be fabricated in the field from the same liner as that shown in the drawings. The boots shall be welded and clamped to polyethylene pipe. They shall be clamped to nonpolyethylene pipe as shown in the drawing to provide a leak-free attachment.

Metal battens—Metal battens shall meet the requirements of Material Specification [594](#) and shall be installed according to the drawings and the liner manufacturer's specifications. The battens shall be bolted to structure concrete by epoxy coated bolts on 6-inch intervals to create a leak-free connection under submerged conditions. Bolt spacing shall be increased to 12 inches for connections above the fluid level.

Embed channel—HDPE embed channel shall meet Material Specification [594](#) and be installed according to drawings and the liner manufacturer's specification. The embed channel shall be prefabricated to the dimensions as shown in the drawings. All sections of the channel shall be welded to the next section continuously to prevent gaps between sections or pieces of the embed channel before their installation in the concrete forms. All corners shall be miter cut and welded all around.

11. GAS VENTS AND DRAINAGE

When specified, gas vent flaps or vent pipes shall be installed in accordance with the drawings to provide adequate venting for the liner system. Drainage systems will be installed as specified and as shown on the drawings.

12. PLACEMENT OF COVER SOIL (OPTIONAL)

Cover soil and its placement method shall be in accordance to the drawings and shall conform to this specification and liner manufacturer's specification. Cover soil material shall not consist of any angular rocks or sharp objects that could damage liner. Placement shall be by a loader or bulldozer. No construction equipment or machinery shall be allowed to drive directly on the liner. A minimum of 12 inches of cover soil is required under the tracks or tires of construction equipment, with ground pressures of less than 5 pounds per square inch, before operating on the liner. The depth of cover soil shall be proportionally higher for heavier equipment. Cover material shall be placed during the cool times of the day or at night to prevent liner folds.

13. PLACEMENT OF CONCRETE

Concrete placement for ramps and other appurtenances shall be in accordance to the drawings and specifications. All reinforcement steel shall be placed on flat-footed plastic rebar chairs. All rebar splices shall be fully tied to avoid loose ends. On slopes, concrete shall be placed from the bottom of the slope to the top and have a low slump to prevent sloughing down slope during placement. Only plastic shovels and internal vibrators shall be used to place concrete. Metal shovels and rodding are not allowed. Concrete forms shall be held in place by methods that avoid damaging the liner.

14. MEASUREMENT AND PAYMENT

For the work for which specific unit prices are established in the contract, the quantity of liner shall be determined to the nearest square foot by measuring the installed liner with a calibrated measuring wheel. The total pay quantity shall include the liner installed in the anchor trench, in areas with double liner, and rub sheets according to the drawings, but shall exclude scrap, waste, overlap, and compensations for expansion and contraction of liner. Such payment shall constitute full compensation for furnishing, shipping, and installing the liner, all pipe boots, mechanical attachments to structures, and other items necessary and incidental to the completion of the work. Payment for items listed separately in the bid schedule shall be made at the contract prices for those items.

GEOSYNTHETIC CLAY LINER

1. **APPLICABILITY**

Construction Specification 98 is applicable to the placement of geosynthetic clay liners in liquid containment systems to control seepage.

2. **MATERIAL SPECIFICATIONS**

Material Specification [595, Geosynthetic Clay Liner](#), complements this specification. Construction Specification [95, Geotextile](#), also complements this specification.

3. **INCLUDED ITEMS**

Items to be included in the contract drawings and specifications follow:

- a. Compaction requirements of the subgrade.
- b. Details of panel placement, orientation, and anchorage.
- c. Requirements of any cushioning material to be used and material references for the same.
- d. Requirements for under drains or interceptors and the associated material.
- e. Physical requirements, depth of placement, and source of the backfill material.
- f. Details for any loading, unloading, or cleanout ramps.
- g. Details for installation at the inlet pipe and at other appurtenances.
- h. Details for fences or other safety features.
- i. Any special instructions related to the materials or the installation.

CONSTRUCTION SPECIFICATION

98. GEOSYNTHETIC CLAY LINER

1. SCOPE

The work shall consist of furnishing and installing a geosynthetic clay liner (GCL) with the necessary appurtenances as shown on the drawings or as specified.

2. MATERIAL

The liner material shall comply with the requirements of Material Specification 595, the applicable provisions in this specification, and those shown on the drawings.

Cover soil shall conform to this specification and those requirements shown on the drawings.

3. SHIPPING AND STORAGE

The liner material shall be transported to the job site in a manner that does not damage the rolls. The rolls shall be handled at the site with equipment capable of safely doing the job with no damage to the material. An appropriately sized core bar in combination with a spreader bar and lifting chains is one alternative. Another alternative is a forklift with a stinger attachment.

At the job site, the rolls shall be stored on a flat dry surface. They shall be kept dry at all times. A covering is recommended to prevent unnecessary stress on the packaging.

4. SUBGRADE PREPARATION

When the GCL is placed, the subgrade shall be a dry, smooth surface that is free of debris, roots, ruts, and stones or any projection of more than 0.5 inch. All projections shall be removed, crushed, or pushed into the surface with a smooth-drum roller. The smooth-drum roller shall be used to remove all irregularities and any abrupt grade changes.

5. GCL INSTALLATION

The contractor shall confine the work to an area that can be completely installed and covered to prevent hydration by the end of the normal working day. Daily completion shall be defined as the full installation of the liner, covering around appurtenances, and placement of the specified cover soils.

The liner rolls may need to be placed with a spreader bar to prevent damage to the ends of the roll. The rolls shall be carefully rolled down the slope and not allowed to unroll freely and out of control. Liner panels may be pulled up from the bottom of the slope, but care must be taken to minimize dragging across the subgrade and damaging the GCL surface. A temporary geosynthetic subgrade covering known as a rub sheet may be used to reduce friction and protect the GCL during placement.

The rolls are placed with the nonwoven geotextile side up and the woven geotextile side against the subgrade. The GCL panels are placed so that the seams are parallel to the direction of the slope. This is also true in the corners. All seams parallel to the slope direction shall be overlapped a minimum of 6 inches. End-of-roll seams shall be located at least 3 feet from the toe or crest of the slope. Seams at the base of the slope shall be a minimum of 6 feet from the toe.

When a roll end seam or joint occurs on a slope, construction adhesive shall be used in the lap area, with the overlap increased to 2 feet and shingled in the direction of the slope. All seam areas or runs shall be augmented with granular bentonite, of the same quality of that encapsulated in the liner, to ensure seam integrity. Granular bentonite shall be dispersed evenly from the panel edge to the lap line at a minimum rate of 1 pound per 4 linear feet continuously along all seams or overlap area. Construction adhesives may be used on seams to keep panels in contact during backfill operations if necessary.

For any penetrations or structures the liner will contact, a small notch shall be cut or dug against the edge of the area. The liner shall be brought up to the appurtenance and trimmed to fit into the notch. The contractor shall then apply granular bentonite or compact a mixture of 1 part bentonite to 4 parts soil (by volume), blended dry, into the bottom half of the notch. The liner shall then be inserted into the notch, with the remaining area in the notch filled with the granular bentonite or the 1 to 4 mixture, and compacted.

The GCL shall be anchored at the top of the slope with a proper anchor trench as shown on the drawings. The GCL is placed in the anchor trench in such a manner that it covers the entire trench bottom, but does not extend up the rear trench wall.

Horizontal joints on the slopes shall be avoided if possible. The GCL shall not be placed in the rain, at times of impending precipitation, or in ponded water. Replace any GCL that has begun to hydrate before cover soil can be placed.

6. REPAIRS DURING INSTALLATION

All damaged or flawed material shall be repaired by completely exposing the affected area, removing all soil or other foreign objects, and placing a patch over the damage with a minimum overlap of 24 inches on all edges. Accessory bentonite shall be placed between the patch and the damaged area at the rate of 1 pound per 4 linear feet of edge, and spread to a 6-inch width. When the above procedures are to be implemented on a sloping surface, the edges of the patch shall be fastened to the repaired liner with construction adhesive in addition to the bentonite-enhanced seam.

7. PROTECTIVE SOIL COVER

A soil cover is placed for both protection of the liner and to provide a loading to develop the designed permeability characteristics of the liner system. The cover

shall be placed to the final depths and moisture content as specified in section 9 of this specification or as shown on the plans.

At all times during the soil cover operation, a minimum of 12 inches of soil material shall be kept between the liner and any equipment being used to spread soil cover. In frequently trafficked areas or roadways, a minimum cover thickness of 2 feet is required. The soil cover on all slopes shall be pushed up the slopes not down the slopes to prevent any downhill stress on the liner material. Avoid any sharp turns and quick starts or stops that could pinch or shift the liner.

8. MEASUREMENT AND PAYMENT

For work for which specific unit prices are established in this contract, the quantity of liner installed shall be determined to the nearest square foot by measurement in place using a calibrated measuring wheel or other method acceptable to both contract parties. The total pay quantity shall include the liner installed in the anchor trench and areas of double liner, but shall exclude scrap, waste, overlap, and compensations for expansion and contraction of the liner. Such payments shall constitute full compensation for furnishing, shipping, and installing the liner including all pipe boots or shirts, mechanical attachments to pipes and structures, and other items necessary and incidental to the completion of the work. Payment for items listed separately in the contract bid schedule shall be made at the contract price for those items.

CONSTRUCTION SPECIFICATION

204. SODDING

1. SCOPE

The work shall consist of preparing the area for sodding, furnishing and placing the sod, fertilizer and lime, stakes, watering and rolling on the designated areas.

2. MATERIALS

All sod shall conform to state and federal laws with respect to inspection and quality. Any inspection certificate required by law to this effect shall accompany each shipment. The sod shall consist of strips or blocks of adapted species as specified in section 7. The sod shall be freshly cut, moist, and have a uniform thickness and quality as specified in section 7.

The limestone, where required, shall be standard agricultural ground limestone or approved equivalent with a moisture content not in excess of 10 percent. The rate of application shall be as specified on the drawings or in section 7.

Fertilizer shall be a commercial grade fertilizer, unless otherwise specified. It shall meet the standard for grade and quality specified by state law. Where furnished from bulk storage, the contractor shall furnish a supplier's certification of analysis and weight. When required by the contract, a representative sample shall be furnished for chemical analysis. Rates and methods of application shall be as specified on the drawings or in section 7.

Stakes used to anchor the sod on slopes and in areas of concentrated flow can be wooden, plastic or metal. They must be long enough to be driven in to firm soil to anchor the sod, generally they shall be 6-8 inches long. Anchoring shall be as specified on the drawings or in section 7.

3. SITE PREPARATION

The entire surface to be sodded shall be uniformly smooth, free of stones, roots, clods and other debris, and conform to the alignments, grade and cross section indicated on the drawings.

At this stage, unless topsoiling or other surface modifying feature is specified, the contractor shall apply the fertilizer and/or lime as required, and mix them into the upper 3 inches of the soil surface. The soil will be re-smoothed, if necessary, and lightly rolled. Prior to laying the sod, the area to be sodded will be dampened if not already in a moist condition. The quantities, techniques and locations of site preparation shall be as specified on the drawings or in section 7.

4. PLACING THE SOD

The sod shall be carefully placed, rolled, and anchored as specified on the drawings or in section 7.

5. ESTABLISHING THE SOD

The contractor shall water the sod after placing, and for a period specified in section 7, to ensure establishment.

6. MEASUREMENT AND PAYMENT

For items of work for which specific unit prices are established in the contract, the total area of surface sodded will be measured to the nearest square yard. Such payment shall constitute full compensation for all materials, labor, equipment, and all other items necessary and incidental to completion of the work.

Compensation for any type of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made subsidiary. Such items and the items to which they are made subsidiary are identified in Section 7 of this specification.

CONSTRUCTION SPECIFICATION

707. DIGGING, TRANSPORTING, PLANTING, AND ESTABLISHMENT OF TREES, SHRUBS AND VINES

1. SCOPE

- a. Description: This work shall consist of digging and preparing plant holes, and of furnishing, transporting, temporary storage, planting and establishment of trees, shrubs, vines and other materials.

It shall also include all incidental operations such as mulching, wrapping, care of living plants and replacement of unsatisfactory plants.

- b. Restrictions:

- (1) Working Conditions: Tree planting shall be performed only when water and soil conditions are favorable for such operations. Operations will be suspended or postponed whenever conditions are unfavorable for such work.
- (2) Equipment: Equipment of a type, size, capacity or condition unsuited for obtaining first class work and expedition of the job shall be restricted to areas designated by the Engineer.

2. MATERIALS

- a. Plants: Trees, Shrubs, Vines and Seedlings. Trees, shrubs, vines and seedlings shall conform to the standards adopted by the American Association of Nurserymen.

- (1) Quality of Plant Material:

- (a) Unless otherwise specified plants shall be high quality nursery grown representatives of their normal species and varieties. They shall have average or normal well developed branches, together with vigorous root systems. Plants shall be free from insects, diseases, sunscald, knots, stubs, or other objectionable disfigurements. Thin weak plants shall not be accepted. Plants must show appearance of normal health and vigor in strict accordance with these specifications.
- (b) Trees shall be free of branches (undetermined) no higher from the ground line than 1/2 the total height of the tree; shall have single leaders, be well branched, and with reasonably straight stems. This requirement shall cover all species unless otherwise specified in detailed specifications.
- (c) Plants shall be true to their name as specified.
- (d) Wherever the word "specimen" is used, it denotes trees that are symmetrical, exceptionally heavy and full branched. When more than one is required, all shall be uniform in size and shape.

(e) The southernmost limits for the source of plant materials shall be one sub-zone south of the site of the work. Plant Hardiness Zones shall be as designated in the current Miscellaneous Publication No. 814, Agricultural Research Service USDA.

(2) Measurement for Size: The size of trees and shrubs is shown on the landscape plans.

(a) Diameter or Caliper Trees up to 4 inch diameter size, shall be measured for diameter 6 inches above the ground line and 12 inches above the ground for larger tree sizes.

(b) Root System: The root system of all plants shall be sufficient to insure plant growth.

1. Bare Root Trees: All bare root trees shall have heavy fibrous root system that has been developed by proper cultural treatment, transplanting and root pruning. The spread of the root system shall be 12 times the trunk diameter (caliper) in inches, plus an additional 6 inches.

CALIPER (in.)	AVERAGE HEIGHT RANGE (ft.)	MINIMUM ROOT SPREAD (in.)
½	5 – 6	12
¾	6 – 8	15
1	8 – 10	18
1 ¼	8 – 10	21
1 ½	10 – 12	24
1 ¾	10 – 12	27
2	12 – 14	30
2 ½	12 – 14	36
3	14 – 16	42

2. Bare Root Shrubs: All bare root shrubs shall have a well branched fibrous root system, the minimum spread of which shall be as follows:

HEIGHT OF PLANT (in.)	MINIMUM SPREAD OF ROOTS (in.)
18 – 24	10
2 – 3	11
3 – 4	14
4 – 5	16
5 - 6	18
6 – 8	20

3. Container Grown Plants. Container grown plants shall be well rooted and established in the container in which they are growing. They shall be grown in the container for a sufficient length of time for the root system to hold the earth when taken from the container, but not long enough to become pot bound. The size of the containers shall be not less than 75 percent of the ball sizes for comparable balled and burlapped plant material. Containers shall be stable and not deteriorated to a degree that will cause breaking up of the root ball during the planting operations.
4. Balled and Burlapped Plants. Balled and burlapped plants shall be dug with a sufficient quantity of earth taken equally on all sides and bottoms of the plants to include the necessary roots to insure growth. The thickness of depth of the balls shall be sufficient to include the depth of the root according to species. The balls shall be prepared in a workmanlike manner and firmly bound.

With relation to the height and trunk diameter of the plants, the top diameter of the balls of earth must be equal or greater than those given in the schedule of minimum sizes in Table 1. It shall be understood that the ball sizes are the minimum that will be accepted for the corresponding height and trunk diameter of the plants. Where soil types, climatic conditions, or infrequent root pruning or transplanting in the nurseries have caused roots greater than 1/2 inch in thickness to extend beyond the above minimum ball diameter, the ball diameter

must be increased so that no roots greater than 1/2 inch in thickness, except tap roots, are cut.

TABLE 1

SHRUBS and SMALL TREES

TREE HEIGHT (ft.)	MINIMUM BALL DIAMETER (in.)
Up to 3	12
3 – 4	13
4 – 5	15
5 – 6	16
6 – 7	18
7 – 8	20
8 – 9	22
9 – 10	24
10 – 12	26
12 – 14	32
14 – 16	36

STANDARD SHADE TREES

TREE CALIPER (in.)	MINIMUM BALL DIAMETER(in.)
Up to 1 ½	18
1 ½ to 2	22
2 to 2 ½	24
2 ½ to 3	28
3 to 3 ½	32
3 ½ to 4	36
4 to 4 ½	40
4 ½ to 5	44
5 to 5 ½	48
5 ½ to 6	52

Ball depth shall be approximately 65% of ball diameter.

5. Collected Stock: When collected plants are specified, the spread of roots, bareroot, shall be 1/3 greater than the spread of roots, bareroot nursery grown. If collected material is moved as balled and burlapped, the minimum ball sizes shall be equal to those specified for the next larger size nursery grown stock, balled and burlapped.

(3) Inspection o Plant Material

- (a) Inspection of plant material will be made at the nursery by the Engineer, or his duly authorized representative, whenever such an examination is deemed needed and practical, and must be in the field (or in storage houses) of the nursery supplying the material. Collected stock will be inspected before digging or lifting.
- (b) Approval of material on such an examination shall not be construed as an acceptance of it. Final acceptance will not be made until the plant material is determined to be in a healthy, growing condition at end of establishment period.
- (c) All plant material, including collected stock, shall comply with the State and Federal laws with respect to inspection for plant diseases and insect infestation. An inspection certificate, required by law to this effect shall accompany each shipment and on arrival the certificate shall be filed with the engineer.

(4) Shipment:

- (a) Each species or variety shall be handled and packed in the manner approved for that plant, having regard for the soil and climatic conditions at the time and place of digging and of delivery, and to the time that will be consumed while in transit of delivery. All precautions that are customary in good trade practice shall be taken to insure the arrival of the plants in good condition.
- (b) Plants shall be packed or covered in such a manner as to insure adequate protection against damage while in transit. The roots of bare root plants shall be carefully protected with wet straw or other suitable material to insure the arrival of the plants at destination with roots in a moist condition.
- (c) When shipment is made by enclosed vehicle, the vehicle shall be adequately ventilated to prevent any "heating" in transit.
- (d) All stock furnished must be legibly tagged with the name or the corresponding key designation as indicated on the plans.

- (e) All material shall conform to size and grade according to the current American Standards for Nursery Stock ASA Z60.1 adopted by the American Association of Nurserymen.
- b. Topsoil: Topsoil shall be free from large roots, sticks, weeds, brush or stones larger than 1 inch in diameter or other litter and waste products. It shall be a loamy mixture having at least 90 percent passing the No. 10 sieve.
- c. Backfill Material: Unless otherwise specified backfill material will consist of a mixture of 3 cubic feet of topsoil and one cubic foot of sand. Fertilizer will not be used unless specified. All backfill material shall be in a loose, friable condition when mixed and at the time of planting. The method of mixing the components shall meet the approval of the Engineer.
- d. Fertilizer: Fertilizer (when required) shall be ready mixed material of an analysis specified on the plans or as directed by the Engineer. In cases where a single nutrient is requested, unless otherwise specified, the analysis will be optional, provided that it carries sufficient filler to insure adequate distribution of the nutrient.

The following information shall be shown on the fertilizer bag or package or on a tag attached thereto:

- (1) Name and address of manufacturer.
 - (2) Name, brand or trade mark.
 - (3) Number of net pounds.
 - (4) Chemical composition or analysis.
 - (5) Guarantee of analysis.
- e. Tree Wrapping Materials :
- (1) The wrapping materials shall be commercially available tree wrapping paper.
 - (2) Cord - Jute twine not less than two ply.
- f. Mulch Material: The mulch material for planting shall be approved by the Engineer. The mulching material shall be uniformly graded and have the ability to completely block sunlight from reaching the surface of the soil. The mulch material will consist of one or more of the following as specified in detailed specifications.
- (1) Processed hardwood tree bark
 - (2) Cottonseed hulls
 - (3) Crushed corn cobs
 - (4) Wood chips
 - (5) Nut shells
 - (6) Buckwheat hulls

- (7) Aggregates
- (8) Small grain straw

g. Materials for staking and guying trees:

(1) Post, stakes, and anchors.

- (a) Metal "tee posts" - length specified in bracing specifications.
- (b) Wooden stakes - 2 1/2" x 2 1/2" length specified in construction details standard drawing [IL-687-2 GUY METHOD-TREES UNDER 8'](#).
- (c) Anchors for guying shall be 36" long wooden 2" x 4"s or auger type anchors, as shown standard drawing [IL-688-3 GUY METHOD TREES OVER 8"](#).

(2) Wire - Malleable No. 12 or larger gauge galvanized annealed steel wire.

(3) Hose - New two-ply reinforced hose having an inside diameter of not less than 1/2 inch.

3. CONSTRUCTION

a. Planting Time: Regardless of calendar date, plants must be dormant at the time they arrive at the site of the work or storage site.

(1) Spring planting of balled and burlapped and container stock shall be performed from the time the soil can be worked until the plant, under field conditions, is not dormant except that: Evergreen planting shall be terminated on June 1 in northern Illinois and May 15 in central and southern Illinois unless otherwise specified in the detailed specifications.

(2) All bare root plant material shall be planted in the spring. It shall be planted only when the temperature exceeds 35 degrees F. Planting shall terminate on May 15 in northern Illinois on May 5 in central Illinois April 25 in southern Illinois.

(3) Fall planting of balled and burlapped stock. This work shall start when the plant (under field conditions) becomes dormant and shall stop when the ground cannot be satisfactorily worked except that evergreen planting shall be performed between September 1 and December 1 in central and southern Illinois unless otherwise specified in the detailed specifications.

(4) Plantings shall not be made in frozen ground, holes shall not be dug in frozen ground and frozen backfill material shall not be used.

b. Digging Plants: Plants shall not be dug until Contractor is ready to transport them or to have them transported from their original locations to the site of the work or

approved storage. The maximum time lapse between digging and being properly loaded for delivery to the site of the work or being placed in approved storage shall be 4 days for balled and burlapped plants and one day for bare root plants. They shall be dug with care avoiding injury to the plants or loss or damage of the roots, particular attention being given to fibrous roots. Immediately after digging, roots shall be protected against drying out and freezing. Bare root plants shall be dug only when air temperatures exceed 35 degrees F. Stock shall not be dug, balled and burlapped when the soil is frozen.

- c. Transportation. During transportation, the contractor or those transporting the plants for the Contractor shall exercise care to prevent injury and drying out of plants. Upon arrival at the temporary storage location or the work site, plants shall be inspected for proper shipping procedures. Should the roots be dried out, large branches broken, ball of earth broken, or loosened, or areas of bark torn, the Engineer may reject the injured tree. When a tree has been so rejected, the Contractor shall at once remove it from the storage: No plant shall remain in temporary storage over the summer or winter unless otherwise specified in the detailed specifications. Plants that are not to be planted immediately shall be protected in the following manner:
- (1) Bare Root Plants may remain on the site of the work only 24 hours prior to being planted or placed in storage. The roots of plants to be placed in storage shall first be puddled in a paste solution of topsoil and water. The plants shall then be protected and kept moist by "heeling-in" the roots or be separated and the roots heeled in a suitable moist soil. If plants are stored in a building, the roots shall be covered with a suitable moist mulch. Planting materials not planted by the end of the planting periods shall be removed from the site and not returned to the site for use.
 - (2) The earth balls of balled and burlapped planting stock shall be kept moist and their solidity carefully preserved. Plants may remain on the work site only 72 hours prior to being planted or placed in storage. To prevent drying out or freezing they shall be stored either in a cool moist storage building or placed in a compact group with a suitable mulch material placed around and between the balls so they are completely covered. The duration of storage and mulch material shall meet the approval of the Engineer.
 - (3) The roots and rooting material of container grown planting stock will be kept moist. To prevent freezing, they shall be stored either in a cool moist storage building or placed in a compact group with a suitable mulch material placed around and between the containers so they are completely covered. The duration of storage for balled and burlapped and container grown deciduous planting stock will terminate in the spring when the plants, under field conditions, break dormancy and in the fall when the ground cannot be satisfactorily worked.

The duration of spring storage for evergreen planting materials shall terminate on June 1 in northern Illinois and on May 15 in central and southern Illinois. Fall storage of evergreen planting material shall terminate on November 1 in Plant Suitability Zone 1 and on December 1 in Plant Suitability Zones II and III.

Planting materials not planted by the end of the storage periods shall be removed from the site and not returned to the site for use.

- e. Layout of Planting. The area to be planted will be finished to line and grade before planting operations are begun. The Contractor shall furnish and place all stakes for locating the planting sites. The stakes will be marked with the species code on the plans. The Contractor will place stakes and outline each area for mass or solid planting or plantings with less than 6' spacing. The spacing and locations of species shall be shown on the plans or as directed by Engineer.
- f. Site Preparation. Unless otherwise specified, the immediate planting areas for trees, shrubs and vines shall be treated prior to planting. An area extending a minimum of 2 feet in all directions from where any plant is to be planted and entire plant beds where the spacing of the plants are 6 feet or less shall be treated. Treatment shall be by either mechanical or chemical means. If a mechanical method is used, the area shall be cultivated to a depth of not less than 2 inches, with equipment approved by the Engineer, until the surface is smooth and free of debris, gullies, clods, stones, grass, weeds and any other living vegetation. If chemical control is used, the treated area does not have to be disturbed prior to planting when the surface is smooth and free of debris, gullies, clods and stones.
- g. Pruning. Pruning shall be the responsibility of the Contractor. It may be done at the nursery or at the planting site in such a manner as to preserve the natural growth habit of the tree, shrub, or vine. Pruning shall meet the approval of the Engineer. All pruning shall be done with sharp tools and in accordance with good horticultural practices.
 - (1) Deciduous Trees. Pruning shall consist of removing twigs and branches as dictated by the growth habit of the trees being pruned. Unless otherwise specified or otherwise directed by the Engineer, branches shall not be removed from a height exceeding 1/2 the total height of the tree, neither shall the leader or terminal buds of the leader be removed unless specified.
 - (2) Deciduous Shrubs. Unless otherwise specified, multi-stemmed shrubs shall be cut back to one-half the height that they attained in the nursery during the previous growing season. Single stemmed shrubs shall be pruned in the same manner as deciduous trees.
 - (3) Evergreens. Evergreens shall not be pruned except to remove broken branches and roots.

The ends of all broken roots and damaged roots shall be pruned before planting. All broken twigs, shrubs, limbs, stubs, and improper cuts from previous pruning shall be removed either before or within 2 days following planting.

- h. Excavation of Plant Holes: The sides of all plant holes shall be sloped to 1:1 or flatter and the bottoms shall be horizontal. On slopes, the depth of excavation shall be measured at the center of the hole. Unless specified in the detailed specifications, watering saucers will be constructed around all single plants where the spacing is 6 feet or more on centers. The saucers shall be a minimum of 4 feet in diameter and a minimum of 4 inches deep unless otherwise specified in detailed specifications. The saucers may be all or partially above or below the normal ground elevation. Material excavated from the plant hole shall be used as needed to construct the watering saucer and the remainder will be disposed of as indicated in the detailed specifications.
- (1) Excavation of holes for planting balled and burlapped or container grown trees, shrubs, or vines. The holes shall be dug at the locations indicated by the stakes or on the plans. They shall be excavated 2 feet greater in diameter than the earthen balls or containers. Unless otherwise specified in the detailed specifications excavate to a depth 1 to 2 inches greater than the depth of the ball or container, plus depth needed for construction of a watering saucer when required.
 - (2) Plant holes for bare rooted trees, shrubs, and vines shall be wide enough and deep enough to accommodate the spread out roots of the plants. The holes will be deep enough to allow the plant to be planted one inch deeper than it grew in the nursery, plus depth needed for construction of a watering saucer when required.
 - (3) When planting trees, shrubs, and vines all stones, debris, and all living herbaceous and wood material, within the area to be mulched shall be killed or removed.
- i. Planting Procedures. All plants shall be planted in the plumb position. Plants will be set at the same depth or up to one inch deeper than they grew in the nursery.

Prepared backfill material shall be placed around the balls of balled and burlapped plants, around the container or mass of soil and roots of container grown plants or around the roots of bare rooted plants being planted in excavated holes. See [standard drawing IL-689 PLANTING PROCEDURES FOR SHRUBS](#) for shrub planting detail and [standard drawing IL-687-2 GUY METHOD-TREES UNDER 8'](#) for tree planting detail or [standard drawing No. IL - 685-PLANTING PROCEDURES FOR BALLED AND BURLAPPED \(B&B\) or CONTAINER-GROWN TREES AND SHRUBS](#).

Tamp the backfill material during placement and thoroughly water after backfilling has been completed. This watering shall completely saturate planting. After the

ground settles, as a result of watering, the voids shall be filled to the proper level with prepared backfill material. Approved watering equipment shall be at the site for the work and in operating condition prior to starting the planting operation.

- (1) Balled and Burlapped Plants. Remove all cords, wires and burlap from the trunk of the plant during or at the end of the backfilling operation.
- (2) Container Grown Plants. Prior to placing the plant in the excavated hole, the container shall be removed with care so as to not disturb the soil in which the root system is growing. Care shall be taken during backfilling operations not to destroy the solidity of the mass of soil. Containers of material that will decompose within one growing season after planting need not be moved.
- (3) Bare Root Plants.
 - (a) When planting in excavated holes the roots shall be carefully spread in a natural position and prepared backfill material shall be worked in around the roots to eliminate air pockets.
 - (b) When planting in a slot made with a tree planting machine or a planting bar (a special planting spade manufactured for planting seedlings), the slot shall be of adequate depth to allow the roots to be fully extended vertically when the seedling is placed in the slot at the proper depth. Care shall be taken when planting to prevent the end of the roots from being turn upward. Pruning for large massive root systems into balance with top growth will help in ease of planting and possibly prevent "J" roots from occurring. After placing the seedling in the slot at the proper depth, the slot shall be completely closed to eliminate all air pockets. These plants shall not be watered unless otherwise specified.
- j. Mulch Cover. Within 5 days after planting, a mulch cover shall be placed around all plants, unless otherwise specified, to control the growth of competing vegetation. Unless otherwise specified an area extending a minimum of 2 feet from any plants spaced greater than 6 feet apart shall be mulched. Where plants are on less than 6 foot spacing the entire bed or areas, plus an area extending a minimum of 3 feet beyond the peripherals of the plants, shall be mulched unless otherwise specified.

Small grain straw shall be relatively free of any viable seed and shall be applied evenly at the rate of 3/4 pound per square foot unless otherwise specified.

All other mulching material shall be applied to a minimum depth of 6 inches. Depth of mulching material should not exceed 6 inches. The mulch shall not be covered with hold down material unless specified in detailed specifications.

- k. Wrapping. Within 10 days after planting, all deciduous trees shall be wrapped from the ground to the lowest major branch unless otherwise specified in detailed specifications.

Unless otherwise specified in the detailed specifications, the following method of wrapping shall be used. Bare root stock does not have to be wrapped.

The tree wrapping paper shall be wrapped tightly around the trunk from the bottom to the lowest major branch with a minimum of one inch overlap. At top and bottom and at 2 intermediate intervals not greater than 18 inches, the wrapping paper shall be secured with ties of stout cord that will stretch with the growth of the tree. Remove after one growing season from fast growing species.

- I. Bracing. Unless otherwise specified all trees over 4 feet in height shall be braced within 10 days after planting.

- (1) Trees 4 to 8 feet tall shall be braced by securing each tree to (2) metal "tee" posts or two (2) 2 1/2" x 2 1/2" wooden stakes. The wooden stakes shall be durable for a minimum for 12 months after being placed in the ground. See standard drawing [IL-687-2 GUY METHOD - TREES UNDER 8'](#).

Use stakes or posts with a minimum length of 6.5 feet if they are placed adjacent to the ball, container or bare rooted plant. Use stakes or post with a minimum length of 6 feet if they are placed a minimum of 6 inches outside the area excavated for planting.

Placement of stakes or posts:

Balled and burlapped - beyond the edge of the ball.

Container stock - beyond the edge of the container.

Bare root stock - 12 to 15 inches from the trunk of the tree.

Place one stake or post on the west side of the tree and one on the east side. Drive the stakes or posts into the ground leaving 4 feet to 4.5 feet above the ground. The anchor plate on the metal post shall be perpendicular to a line between the tree and the post.

Secure each tree firmly to each of the two posts or stakes with No. 12 or larger malleable wire. The wires shall be installed on a horizontal plane at a height approximately one half that of the tree. The portion of the wire in contact with the tree shall be enclosed in 1/2" two ply reinforced hose.

The area inside the loop around the tree shall not be less than 2 times the cross sectional area of the tree at the contact point. Provisions shall be made to tighten the wires if they become loose.

- (2) Trees over 8 ft. in height shall be braced by using 3 guy wires and 3 anchors per tree. See standard drawing [IL-688-3 GUY METHOD - TREES OVER 8'](#). The guy wires shall be placed around the tree immediately above branches located from one-half to two-thirds the height of the tree. No more than one

guy wire shall be placed above any branch if a higher branch exists. The portion of the guy wire that contacts the tree shall be enclosed in the 1/2" two ply reinforced hose. The inside area of the loop around the tree shall not be less than 2 times the cross sectional area of the tree at the point of contact.

The guy wire shall be securely fastened to an anchor post or stake, at or below the ground line, which is driven at least 30 inches into the ground at an angle that is perpendicular to the line of pull. Distance of anchors from the base of the tree shall not be less than two-thirds nor greater than the vertical distance from the base of the tree and the point where the guy wire contacts the tree.

One anchor shall be placed on the west side of the tree and the others placed so all guy wires are equidistant. Provision will be made to tighten the guy wires if they become loose.

4. ESTABLISHMENT

During the period of establishment, the Contractor shall be responsible for properly caring for plants to assure maximum possible survival and vigorous healthy plants. Such care will consist of, but not be limited to the following work:

- a. Watering
- b. Replenishing mulch
- c. Repairing stakes, guy wire, etc.
- d. Restoring saucers
- e. Weeding
- f. Seasonal spraying (insect/disease problems)
- g. Repairing tree wrapping and ties
- h. Fertilizing
- i. Application of herbicide

The period of establishment shall extend from the time the plants are planted through the month of September and shall not be less than ninety (90) calendar days.

5. GUARANTEE

Prior to the September following the planting operations, the Contractor shall contact the Engineer to inspect the planted areas. At the end of the establishment period in September, the Engineer will determine the number and species of missing, dead, diseased, or unhealthy plants and will inform the Contractor in writing which plants are rejected. All rejected plants shall be replaced, within the next appropriate planting period.

No additional guarantee will be required for replacement plants. The guarantee and establishment period will end on the date of this inspection and said inspection will

be considered final provided the Contractor has complied with the following requirements:

- a. Complete replacement of dead, missing, and defective plant material.
- b. Mulch and weed plant beds and plant saucers. Just prior to this inspection, treat these areas to an application of approved pre-emergence herbicide, if chemical site preparation was originally used.
- c. Assure stakes, guys, and required tree wrappings are in good condition.
- d. Complete remedial measures directed by the Engineer to ensure plant survival.
- e. Repair damage caused while making plant replacements.

6. SUPPLEMENTAL WATERING OF PLANTINGS

This work shall consist of supplemental watering of plantings. Supplemental watering of balled and burlapped, containerized planting stock and bare root planting stock planted in excavated holes shall be performed at least once every 30 days from the date of planting until the month of September, unless the Engineer determines that it is needed more or less often due to moisture provided by rainfall. Slot planted trees, shrubs, and vines shall not be watered. Sufficient water will be applied at each watering to thoroughly saturate the soil in an area extending a minimum of 12 inches beyond and below the sides and bottom of the hole excavated for planting.

7. MEASUREMENT AND PAYMENT

For items for which specific unit prices are established in the contract, each type and size of plant will be counted. Payment for each type and size of plant will be made at a contract unit price for that type and size of plant. Such payment will constitute full compensation for all labor, materials, equipment and other items necessary and incidental to the performance of the work including:

- a. Replacement of any plants required to fulfill the guarantee provision of this specification.
- b. Removal from the site and replacement of any planting stock not conforming to the specification.
- c. Care of plants during period of establishment.

The supplemental water shall be measured and paid for at the contract unit price per 1,000 gallons of water applied. Such payment shall constitute full compensation for all labor, equipment, materials, and all other items necessary and incidental to watering.

Compensation for any items of work described in the contract but not listed in the bid schedule will be included in the payment for the item of work to which it is made

subsidiary. Such items and the items to which they are subsidiary are identified in the detailed specifications.

CONSTRUCTION SPECIFICATION

750. USE OF DORMANT WOODY PLANTINGS FOR STREAMBANK STABILIZATION

1. SCOPE

Dormant woody planting, as referred to in Practice Standard [995-Vegetative Streambank Stabilization](#), is the use of live dormant stem cuttings of woody plant species of one-half inch to over three (3) inches in diameter for the purpose of vegetatively reproducing a selected tree or shrub species. This work shall consist of furnishing and installing the necessary vegetative materials, woody or grass species, as specified in Section 7 of this specification or related standard drawings.

2. PREPARATION AND HANDLING OF MATERIALS

The proper preparation and handling of selected materials is very important. The following guidelines will increase the chances of success:

- a. Always select healthy materials native or adaptable to the planting site.
- b. Make clean cuts and avoid split ends. Cutting tools to be used, including pruning shears, bow saws, chain saws, etc., should be based on the diameter of materials to be cut.
- c. Always plant materials with the butt end down. The butt end should be tapered to mark it for proper orientation as well as facilitate driving it into the soil if done so manually. The top end should be flat, especially on stakes and posts, to facilitate manual driving (see Figure 1).
- d. Trim lateral branches as shown in Figure 1 to leave the bark ridge and branch collar intact.
- e. The diameter and length of the plant materials varies with the type:

Dormant "cutting" - The diameter of cuttings shall be a minimum of one-half inch and a maximum of less than one (1) inch. Cuttings shall be at least 12 inches but less than 18 inches in length.

Dormant "stake" - "Stakes" will be one (1) to three (3) inches in diameter at the top and 30 inches to six (6) feet in length.

Dormant "Posts" - "Posts" will be greater than three (3) inches in diameter at the top end. Length will vary with the depth to saturated soil and the difference in feet between the channel bottom and low bank elevation. However, posts will be a minimum length equal to the difference in feet between the lowest point of channel scour and the low bank elevations or 7 feet, whichever is less.

All "stakes" and "posts" shall extend a minimum of two (2) feet below the maximum depth of the streambed scour.

- f. At least two (2) lateral buds and/or terminal bud scars will be above the ground on "cuttings". It is recommended that a terminal bud scar be located within 1 to 4 inches of the top. Cuttings put out the largest number and strongest shoots just below a terminal bud scar (annual growth scar).
- g. Planting materials must not be allowed to dry out. They will be kept moist and covered during transport to the planting site and during planting operations. Material will be kept submerged in water up to the time of planting. It is best to plant materials the same day they are cut and prepared. One exception to this is eastern cottonwood which has exhibited increased survival rates if soaked in water for 1 to 2 days prior to planting.

3. SITE EVALUATION

A number of considerations will be addressed during the planning and design phases of a streambank stabilization project. Some of these considerations include:

- a. Streambank Characteristics - What is the stream channel bottom to low bank height difference for determining minimum "post" length, the existing bank slope or planned bankslope to determine the row placement requirements, and the existing vegetation in relation to its incorporation into the final project design?
- b. Soil Types - What soil type(s) are present and what plant species will grow well on the site, especially in relation to tree, shrub and grass/legume species planted in the riparian zone? How stable are the soil types present on the project site(s)?
- c. Stream Channel Characteristics - The important consideration here is the stability of the channel bottom. This method of stabilization will be limited to those streams with a stable channel bottom characterized by the lack of channel scour and overfalls and having a typical "meandering" channel.

See "Streambank Stabilization Site Evaluation Worksheet" at the end of this specification for additional information.

- d. Equipment, Time and Costs - Based on the above items, what kind of equipment will be needed to prepare the site and install the planting materials? How many man-hours will be required to complete the project? How much will it cost, including equipment, materials and labor?

4. SPECIES TO PLANT

For dormant planting materials, select native or naturalized species that are known to root readily with or without the use of rooting hormones. Rooting hormones, if used, shall be applied according to manufacturers' recommendations. Eastern cottonwood (*Populus deltoides*) and Black willow (*Salix nigra*) are native species which root readily without hormonal treatments.

Woody species with short, dense, flexible top growth and large, deep, fibrous root systems are recommended. Other desirable characteristics include rapid initial growth, ability to reproduce by seed or vegetatively, and resistance to insects and diseases.

Species suitable for use as planting materials or bare-root planting stock are listed in Table 1.

5. DESIGN AND LAYOUT

Spacing of dormant "stakes" and "posts" will be on 2'x 2', 2'x4', or 4'x4' staggered spacings. Dormant "cuttings" may be scattered between rows of "stakes" and "posts" in Plant Zone 1 and the lower one-half of Plant Zone 2 (see Figure 3 for a sample layout).

On eroding streambanks over 15 feet high, a minimum of 4 rows of dormant "stakes" or "posts" will be included in the design.

Planting row arrangement shall conform to those minimums listed in the standard and specification for this practice (see Figure 4).

6. INSTALLATION

Dormant planting materials must be properly installed to improve the chances of success. The following guidelines shall be followed:

- a. Be sure that the planting material is planted correctly. (Butt end in the ground.)
- b. Set the materials as deep as possible with at least the bottom 12 inches into a saturated soil layer. Deep planting insures an adequate moisture supply for root development, minimizes water loss due to transpiration and prevents root breakage caused by movement between the planting material and the soil during high velocity water flows.
- c. Avoid excessive damage to the bark of the planting material, especially stripping.
- d. Be sure there is good contact between the soil and planting material. "Dormant cuttings" will have the soil tamped around them. Dormant materials may be installed using an iron bar for "cuttings" and a post hole digger, powered auger or a metal ram on a backhoe or similar equipment for "stakes" and "posts". In soft, non-restricted soils, "stakes" or "posts" may be manually driven into place using a wooden maul. If a sledge is used, care must be taken to avoid splitting the planting material. Extreme care in driving the stakes or posts is needed and shall be limited to those soils where use of the other methods is not feasible, such as sandy soils. Post lengths will be extended 4" to 6" to allow for a new flat cut to eliminate any damaged materials after manual driving. At least 40 percent, and preferably 50 percent or more, of the planting material shall be below ground level after planting.

- e. Where damage by beaver may occur, treating materials with a repellent, such as ropel, or enclosing them with chicken wire is recommended.
- f. All "stakes" and "posts" located in the stream channel shall have a minimum of 12 inches extending above the normal water level.

All materials will be cut and installed while in a dormant stage. Therefore, the following periods will be used for practice installation: November 1 until ground becomes frozen or February 1 to April 1 provided ground is not frozen or buds have not broken dormancy.

7. SPECIAL SITE SPECIFICATIONS

Species selection shall consider the position of the plant in the bank profile (see Figure 2).

Zone 1 - Below normal waterline to upper limit of saturation area kept moist by capillary water movement. This zone includes the greatest potential for periodic inundation and the least moisture stress.

Zone 2 - Area from upper limit of Zone 1 to 2-3 feet from the top of the bank. This area may be subject to rapid drying and greater moisture stress.

Zone 3 - Area 2-3 feet below the top of the bank to a minimum of 30 feet into the floodplain (riparian area)

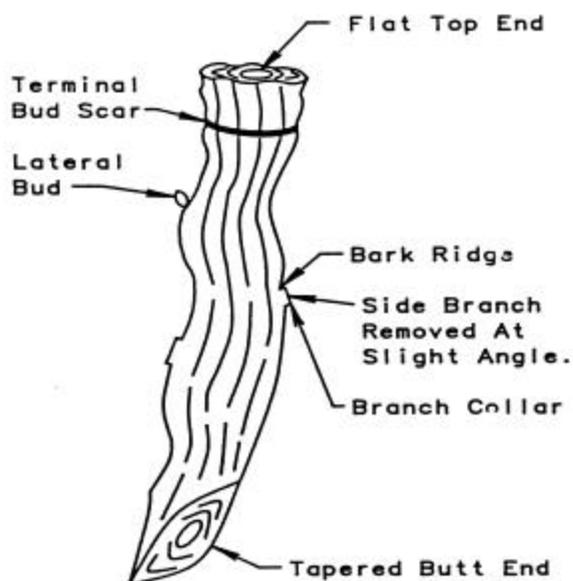

Table 1.
Recommended Woody Species for Streambank and Shoreline Protection

<u>Plant Zone</u>	<u>Common Name</u>	<u>Genus Species</u>	<u>Growth Form</u>
1	*Black Willow	Salix nigra	Tree
1	*Bankers Willow	Salix cottettii	Shrub
1	*Purple-osier Willow	Salix purpurea	Shrub
1	*Sandbar Willow	Salix interior	Tree
1	*Carolina Willow	Salix caroliniana	Tree
1	*Peach-leaved Willow	Salix amygdaloides	Tree
1	*Buttonbush	Cephalanthis occidentalis	Shrub
1,2,3	*Red-osier Dogwood	Cornus stolonifera	Shrub
2,3	*Silky Dogwood	Cornus amomum	Shrub
2,3	Flowering Dogwood	Cornus florida	Tree
2,3	Green Ash	Fraxinus pennsylvanica	Tree
2,3	*Sycamore	Platanus occidentalis	Tree
1,2,3	Baldcypress	Taxodium distichum	Tree
1,2	River Birch	Betula nigra	Tree
1,2,3	*Eastern Cottonwood	Populus deltoides	Tree
1,2,3	*Swamp Cottonwood	Populus heterophylla	Tree

* These species are suitable for use as dormant woody cuttings, stakes or posts. All species of willow and cottonwood do not require hormone treatment for rooting.

Any deciduous hardwood species listed in the corresponding Woodland Planting Group in the NRCS Field Office Technical Guide for the applicable soil type is suitable for planting as bareroot stock in zones 2 and 3.

Figure 1
Planting Material Preparation

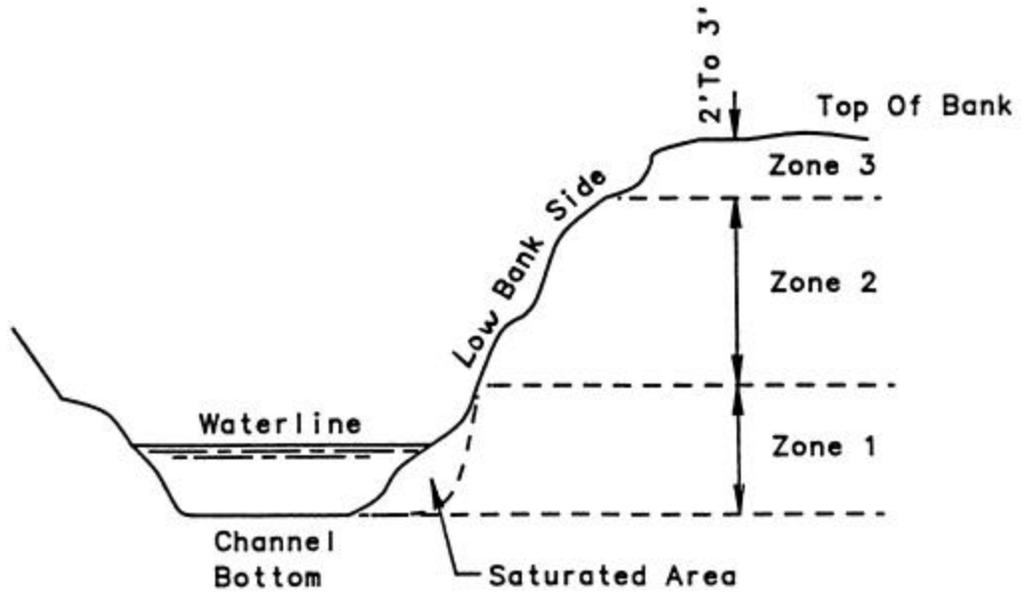

Figure 2
Plant Zones

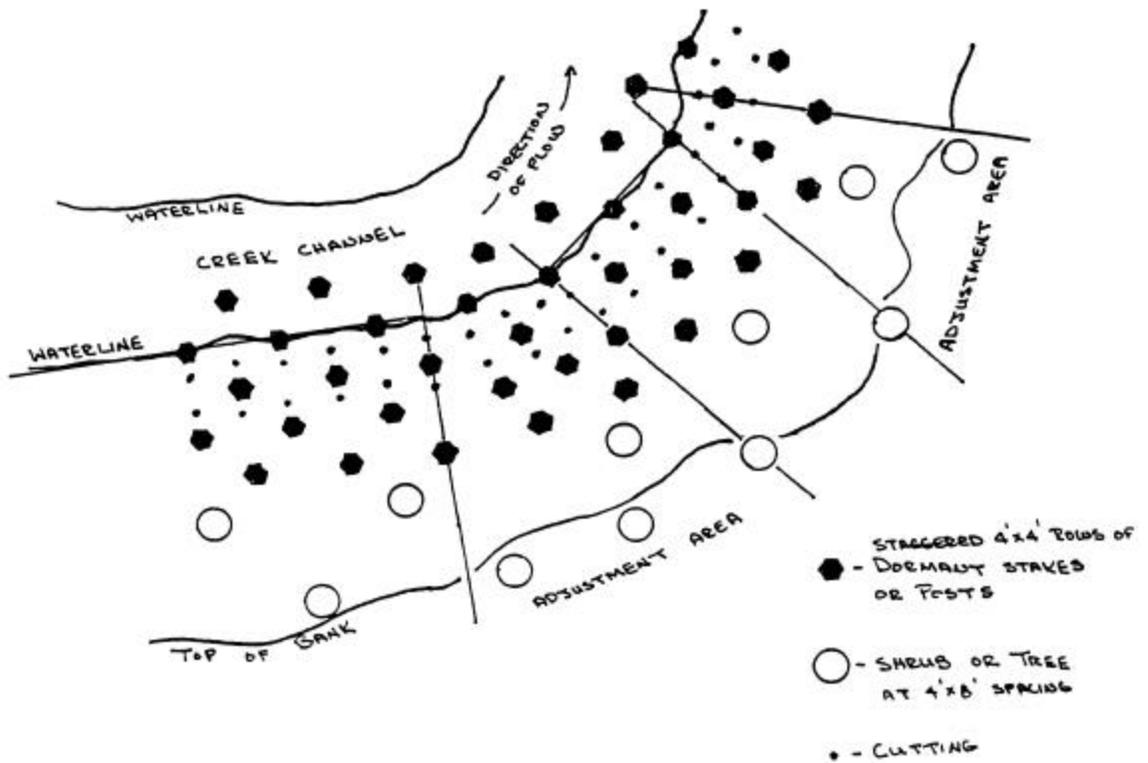

Figure 3
Sample Layout

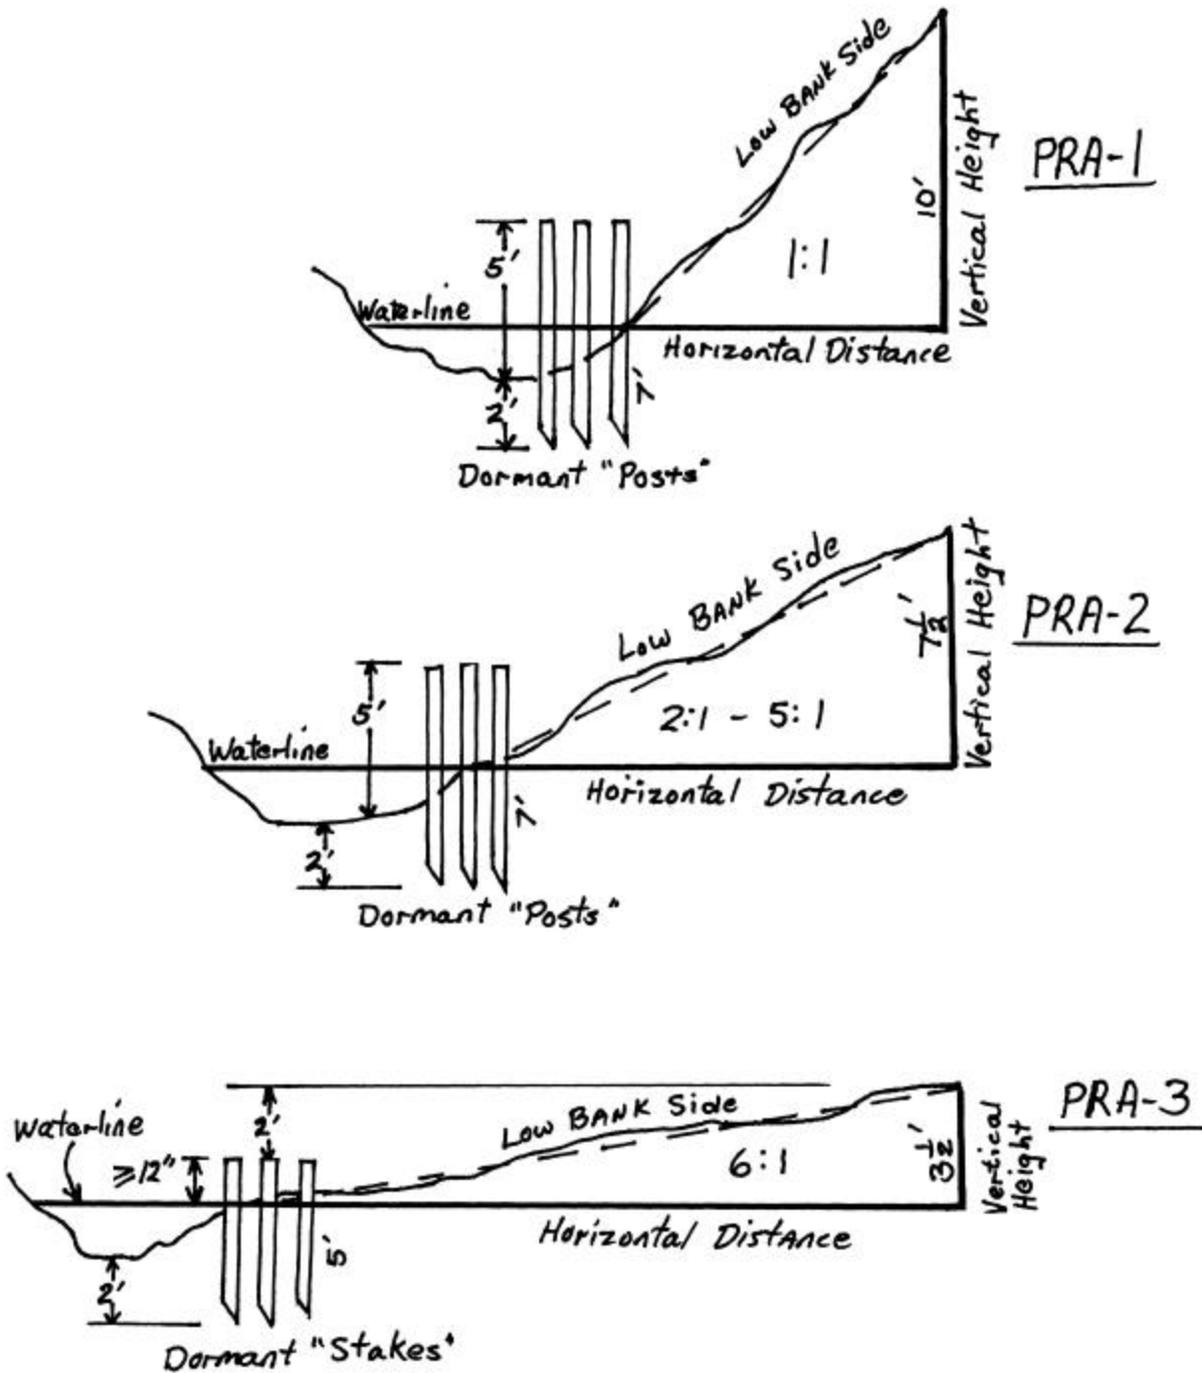

Figure 4
Minimum Planting Row Arrangements (PRA)

STREAMBANK STABILIZATION SITE EVALUATION WORKSHEET

1. Determine channel bottom to low bank height differences:

A = Elevation of low bank at lowest point on its profile = _____

B = Elevation of channel bottom at lowest point of channel scour = _____

C = Difference in elevation (A - B) = _____

2. Determine minimum length of "stake" or "post" required:

If difference (C) exceeds 5 feet – Use a minimum length of 7 feet.

If difference (C) is less than 5 feet – Use a minimum length equal to C.

3. Determine the ratio of horizontal distance to vertical height of the streambank (low bank side) for row arrangement to be used (see figure 4):

Example: Horizontal distance of streambank equals 12 feet vertical height of streambank equals 6 feet Horizontal distance to vertical height ratio equals 12:6 or 2:1

Horizontal Distance to Vertical Height Ratio	Minimum Planting Row Arrangement to Use
Steeper than 2:1	PRA-1
2:1 to 5:1	PRA-2
Flatter than 5:1	PRA-3

4. Will it be necessary to regrade the streambank to a different ratio? If yes:

A. To what ratio will the completed project be graded? ____:____

B. Based on "A" above, what PRA will be used? PRA-____

C. What equipment will be needed to complete the regrading? _____

5. Determine soil type(s) at the project site:

A. Predominant soil type(s) in the riparian zone for design purposes: _____

B. Other major soil types present: _____

C. Determine Woodland Planting Group(s) (WPG) to use from Section II-F of the Field Office Technical Guide.

<u>Predominant Soil Type(s)</u>	<u>WPG</u>	<u>Species to be Used</u>
1. _____	_____	_____
2. _____	_____	_____
3. _____	_____	_____

D. Are predominant soil type(s) considered stable if properly protected? _____
 If no, what alternative actions might be needed to assure stability? _____

6. Determine stream channel bottom stability:

- A. Does stream channel bottom have "overfalls" in or immediately below the project site? _____
- B. Does the stream channel bottom continuously fluctuate in elevation due to scour holes? _____
- C. Does the stream have segments of rushing water in an otherwise tranquil stream flow? _____

If any of the above can be answered "yes," careful evaluation by an experienced hydrologist may be needed before designing or installing this project.

7. Determine cost estimates: 1/

- A. Equipment: _____ hours x _____/hour \$ _____
 - B. Labor: _____ hours x _____/hour \$ _____
 - C. Materials: _____ \$ _____
- Total \$ _____

1/ Average cost of \$77/100' length for sloping 12' high bank to 1:1 slope. Cost per hole @ \$2.40/6' post and \$2.90/9' post. Average of 10 posts/person/hour labor costs for cutting and transporting posts.

CONSTRUCTION SPECIFICATION

751. USE OF GRASSES FOR STREAMBANK STABILIZATION

1. SCOPE

Where a good seedbed can be prepared and on smaller streams where flow velocities are less than 5 feet per second, it may be feasible to stabilize eroding streambanks by seeding grasses above or in combination with dormant woody plantings. This work shall consist of furnishing and installing the necessary materials as specified in Section 7 of this specification.

2. SEEDBED PREPARATION

The seedbed shall be roughened with a rake or similar tool and fertilized with 1000 lbs. per acre of 12-12-12- (23 lbs./1000 square feet) or bulk equivalent.

For projects where seeding will be done as construction progresses during seeding periods, apply any required fertilizer and seed within 24 hours after final shaping of the streambanks is completed.

3. SEED

Seed will be clean and relatively free of weed seed and other contaminants. Wet, moldy or otherwise damaged seed will not be acceptable. Seed, except warm season grasses, with less than 80% pure live seed will not be acceptable.

$$\% \text{ pure live seed (PLS)} = \frac{\% \text{ germination} \times \% \text{ purity}}{100}$$

Percent hard seed will be added to percent germination to determine total percent germination for warm season grasses and legumes.

All legumes not preinoculated will be inoculated with a pure culture of nitrogen-fixing bacteria, specifically formulated for the species, within 12 hours of seeding.

4. PLANT SELECTION AND ESTABLISHMENT

The grass or grass mixture to be seeded will be selected from Table 1 of this construction specification based on the soil/site conditions present at the planting site and the objectives of the project. A companion crop of spring oats, rye or wheat will be included in all permanent seeding mixtures per Table 1 seeding mixture rates.

A temporary seeding or mulching will be completed on those sites where a permanent seeding will not be established within 30 days following installation of a project. Temporary seeding will consist of a species or mixture of species as listed in Table 1 of this construction specification. Temporary mulching will be completed in conformance with guidelines provided in PRACTICE STANDARD [875-MULCHING](#) and any applicable construction or material specifications and standard drawings.

Seeding of the selected grass or grass mixture will be completed using one of the following methods:

- a. Conventional Method - Prepare a seedbed as instructed in the section "Seedbed Preparation" and uniformly apply the seed or seeding mixture at the required rate(s). Cover the seed with a rake or similar tool to a depth of 1/4 to 1/2 inch.
- b. Dormant Seeding - Prepare a seedbed as instructed in the section "Seedbed Preparation". Apply and anchor mulch in conformance with PRACTICE STANDARD 875 - MULCHING. Broadcast seed or hydroseed over the top of mulch during dormant seeding periods.
- c. Hydroseeding - Seed, fertilizer and lime may be applied together using no more than 125 pounds of solids per 100 gallons of water. If legume seed is hydroseeded, triple the recommended rate of inoculant. Hydrated lime will not be used in a slurry mix.

5. SEEDING PERIODS

All seedings will be completed within the seeding period shown on the plans for the appropriate seeding mixture and location in the state in which the project site is located.

6. MAINTENANCE

Sites will be protected from damage by vehicular and human traffic for a length of time necessary to get the vegetative cover well established but no less than one full growing season.

To improve the establishment of vegetative grass cover, topdress late summer seeding the spring following seeding and spring seeding in late August or early September with 2.5 pounds of actual nitrogen per 1000 square feet of surface area.

Weeds will be controlled by mowing where bank slopes make this feasible. Otherwise, weeds will be controlled by other mechanical means or through the use of environmentally safe and acceptable herbicides which are labeled for this purpose and site situation.

Damaged areas or those sites where additional cover is needed following the establishment period, will be reseeded during the next recommended seeding period as shown in Table 1.

CONSTRUCTION SPECIFICATION

752. STRIPPING, STOCKPILING, SITE PREPARATION, AND SPREADING TOPSOIL

1. SCOPE

The work shall consist of stripping, stockpiling, site preparation, and spreading topsoil in accordance with the applicable specifications.

2. STRIPPING

Strip topsoil only from those areas that will be disturbed by excavation, filling, road building, or compaction by equipment. A 4 to 6 inch stripping depth is common, but depth varies depending on site.

Determine depth of stripping by taking soil cores at several locations within each area to be stripped. Topsoil depth generally varies along a gradient from hilltop to toe of the slope.

All planned erosion and sediment control practices shall be in place and functioning properly prior to stripping.

3. STOCKPILING

Select a stockpile location to avoid slopes and natural drainageways, and to avoid traffic routes. On large sites, respreading is easier and more economical when topsoil is stockpiled in small piles located near areas where they will be used.

Perimeter controls shall be placed around the stockpile immediately. Examples of suitable control measures include [DIVERSION DIKE 820](#), [SILT FENCE 920](#), and [STRAW BALE BARRIER 935](#).

Temporary stabilization of the stockpile shall be completed within seven (7) days of the formation of the stockpile, in accordance with practice standard [TEMPORARY SEEDING 965](#), if it is to remain dormant (undisturbed) for longer than thirty (30) days.

Permanent stabilization of the stockpile shall be completed within seven (7) days of the formation of the stockpile, in accordance with practice standard [PERMANENT VEGETATION 880](#), if it is to remain dormant (undisturbed) for longer than 12 months.

4. SITE PREPARATION

Before spreading topsoil, assure that all necessary erosion and sediment control practices such as diversions, berms, dikes, waterways, and sediment basins are in place and functioning properly. These practices must be maintained until the site is permanently stabilized.

Grading - Maintain grades on the areas to be topsoiled according to the approved plan and do not alter them by adding topsoil.

Liming of subsoil - Where the pH of the existing subsoil is 6.0 or less, or the soil is composed of heavy clays, incorporate agricultural limestone in amounts recommended by soil tests or specified for the seeding mixture to be used (Practice

PERMANENT VEGETATION 880). Incorporate lime to a depth of at least 2 inches by disking.

Roughening - Immediately prior to spreading the topsoil, loosen the subgrade by disking or scarifying to a depth of at least 4 inches, to ensure bonding of the topsoil and subsoil. If no amendments have been incorporated, loosen the soil to a depth of at least 6 inches before spreading the topsoil.

5. SPREADING TOPSOIL

Uniformly distribute topsoil to a minimum compacted depth of 2 inches on 3:1 slopes and 4 inches on flatter slopes. To determine the volume of topsoil required for application to various depths, use Table 1.

Topsoil shall not be spread while it is frozen or muddy or when the subsoil is frozen or muddy.

Irregularities in the surface that result from topsoiling or other operations shall be corrected to prevent the formation of depressions or water pockets.

Compact the topsoil enough to ensure good contact with the underlying soil, but avoid excessive compaction, as it increases runoff and inhibits seed germination and seedling growth. Light packing with a roller is recommended where high-maintenance turf is to be established.

In areas that are not going to be mowed, the surface shall be left rough.

TABLE 1
CUBIC YARDS OF TOPSOIL REQUIRED
FOR APPLICATION TO VARIOUS DEPTHS

DEPTH (in.)	PER 1,000 FT. ²	PER ACRE
2	6.2	269
3	9.3	403
4	12.3	537

SECTION 6 - MATERIAL SPECIFICATIONS

INTRODUCTION

This section contains material specifications. The material specifications are from the NRCS's National Engineering Handbook (NEH) Series Part 642 (formerly referred to as NEH Section 20) as well as several state interim specifications. The interim specifications are numbered starting at 800. The material specifications along with construction specifications (see Section 5) make up the contract specifications and can be used as the requirements in construction contracts. The materials selected will be shown on the drawings and/or also in the construction specifications.

See the general discussion in Section 5 for a description on specifications (construction and material) and their use in construction contracts.

Current updates of material specifications from NRCS's National Engineering Handbook Series Part 642 can be found at <http://www.ftw.nrcs.usda.gov/nehms.html>. The notice for the May 2001 release of the construction specifications in Part 642 identified revisions to Material Specification 523 - Rock for Riprap and Material Specification 581 - Metal. These changes are reflected in this release of Chapter 6 of the Illinois Urban Manual. The dates on the other material specifications have not been updated; however, the technical content of all other material specifications has not likely changed.

This section was updated in November 2002.

MATERIAL SPECIFICATION

511. STEEL PILES

1. SCOPE

The specification covers the type and quality of steel piles.

2. BEARING PILES

Steel bearing piles shall be structural steel H-piles conforming to the requirements of ASTM A 36.

The required length of pile may be fabricated by butt welding shorter lengths of pile stock. Unless otherwise specified, the cross-section of each pile shall be constant throughout its length. The axis of the pile shall be straight and the number of welded joints in the length of the pile shall be as few as practicable. Pieces below the top piece shall have a minimum length of ten (10) feet.

3. SHEET PILES

Steel sheet piles shall conform to the requirements of ASTM A 328, A 572 or A 690.

Fabrication of piles from shorter lengths of pile stock will not be permitted.

MATERIAL SPECIFICATION

512. WOOD PILES

1. SCOPE

This specification covers the quality of wood piles.

2. QUALITY OF PILES

The piles shall conform to the requirements of ASTM D 25 for the specified classes and sizes of piles.

3. TREATMENT

Piles shall be treated with the specified type and amount of preservative and in conformance with the requirements of Material Specification [585](#).

4. MARKING

Each treated pile delivered to the job site shall be marked as specified in Material Specification [585](#).

MATERIAL SPECIFICATION

513. PRE-CAST CONCRETE PILES

1. SCOPE

This specification covers the quality of pre-cast concrete piles.

2. GENERAL REQUIREMENTS

The piles shall conform to the details shown on the drawings. The piles shall be cast of portland cement concrete mixed, placed, and cured by the methods specified in Construction Specification 31, except as amended in the specification. The finished piles shall be true to line with smooth surfaces free from stone pockets, honeycomb or other surface defects.

3. CLASSES OF CONCRETE

Unless otherwise specified, Class 4000 concrete applies.

4. REINFORCEMENT

Reinforcement steel shall conform to the requirements of Construction Specification 34.

5. FORMS

Forms shall be constructed of plywood, metal or dressed lumber and shall have one (1) inch chamfer strips at all corners. They shall be mortar tight, true to line and adequately supported to prevent deformation or settlement during concrete placement. They shall be designed to be removable without damaging the completed piles.

6. PLACING CONCRETE

The concrete shall be placed in each pile in one continuous operation. The concrete shall be compacted and worked into the forms and around the reinforcement by procedures outlined in Construction Specification 31.

7. CURING

The piles shall be cured for a minimum period of 14 days by a method specified in Construction Specification 31.

Test cylinders cast for the purpose of determining when the piles may be subjected to handling stresses shall be cured by the same method as the pile, at the same location and under the same conditions as those applied to the piles.

The steam curing process may be used as an alternative to moist curing or membrane curing. The piles shall be cured in-place on the casting bed by the introduction of steam into a steam tight housing that completely encloses the casting

bed. The first application of steam shall be applied after the concrete has gained an initial set but in no case sooner than two (2) hours after the concrete is placed unless a set-retarding admixture is an ingredient of the approved concrete mix. When a set-retarding admixture is used, the first application of steam shall be applied no sooner than four (4) hours after the concrete is placed. Moist curing methods shall be applied during the interval between the placement of the concrete and the application of the steam.

The steam shall be at 100 percent relative humidity and shall not be applied directly on the concrete. During application of the steam, the ambient air temperature within the housing shall be increased at a maximum rate of 40° F per hour until the maximum temperature is reached. The temperature within the housing shall be maintained between 140° F and 160° F until the concrete has reached the specified strength. In discontinuing the application of the steam, the ambient air temperature within the housing shall be decreased at a maximum rate of 40° F per hour until the temperature within the housing is not more than 20° F above the ambient air temperature outside the housing.

The concrete shall not be exposed to temperatures below freezing for a minimum of six (6) days after placement.

8. REMOVING FORMS

Side forms shall remain in place a minimum 24 hours.

9. HANDLING AND STORING PILES

The contractor shall handle and store piles by methods that will not cause spalling, cracking or other damage to the piles. The Contractor shall furnish all bridles, slings and other handling equipment as necessary.

Piles shall not be moved until the tests indicate a minimum compressive strength of 80 percent of the design 28-day compressive strength. Piles shall not be transported or driven until the field cure test cylinders indicate a minimum compressive strength equal to the design 28-day compressive strength.

Piles that are cracked, spalled or otherwise damaged during handling will be rejected.

MATERIAL SPECIFICATION

514. CAST-IN-PLACE CONCRETE PILES WITH-SHELLS

1. SCOPE

This specification outlines the quality of piles formed by driving shells to the required bearing, leaving the shells permanently in place, and placing concrete within the shells.

2. GENERAL REQUIREMENTS

The piles may have constant diameter or may be tapered. The diameter of the tapered pile shall increase uniformly from bottom to top. The pile may be stepped increasing in diameter from bottom to top with the diameter changes between steps to be gradual and uniform throughout the total pile length. Unless otherwise specified, the average diameter of each pile shall not be less than eleven (11) inches. The minimum tip diameter of a tapered pile shall be eight inches.

3. SHELL

The shell shall be made of reinforced concrete or steel. It shall have sufficient strength and rigidity to prevent distortion during driving or after driving by soil or water pressures or pressures caused by the driving of adjacent piles. It shall be sufficiently watertight to exclude water during placement of concrete. Driven shells shall be clean and free of water before reinforcing steel and/or concrete is placed.

4. REINFORCEMENT

When internal reinforcement is specified, it shall conform to the details on the drawings and to the requirements of Construction Specification [34](#).

5. CONCRETE

Concrete shall not be placed in any pile until the driven shell complete with reinforcement in-place has been inspected and approved by the Engineer.

Unless otherwise specified, the concrete: (1) shall conform to the requirements of Construction Specification [31](#), and shall be Class 4000; (2) shall be placed in each pile in one continuous operation; and, (3) shall be placed and consolidated into the shell in conformance with the requirements of Construction Specification [31](#).

MATERIAL SPECIFICATION

521. AGGREGATES FOR DRAINFILL AND FILTERS

1. SCOPE

This specification covers the quality of mineral aggregates for the construction of drainfill and filters.

2. QUALITY

Drainfill and filter aggregates shall be sand, gravel or crushed stone or mixtures thereof. Aggregates shall be composed of clean, hard, durable mineral particles free from organic matter, clay balls, soft particles or other substances that would interfere with the free-draining properties of the aggregates.

Coarse aggregate may be crushed limestone or other materials with limestone particles included. Aggregates from crushed limestone shall be thoroughly washed and screened to remove limestone dust, limestone fines, and fine soil particles. For coarse aggregate containing limestone, the total portion finer than the No. 4 sieve shall not contain more than three (3) percent by weight of limestone. Limestone shall not be used for fine aggregates except in combination with other materials such that not more than five (5) percent of the portion finer than the No. 4 sieve shall be limestone.

Aggregates shall be tested for soundness according to ASTM Method C 88, and shall have a weighted average loss in five (5) cycles of not more than twelve (12) percent when sodium sulfate is used or eighteen (18) percent when magnesium sulfate is used.

3. GRADING

Drainfill and filter aggregates shall conform to the specified grading limits after being placed or after being compacted when compaction is specified. Grading shall be determined by ASTM Method C 136. The percentage of material finer than the No. 200 sieve shall be determined by the method in ASTM Designation C 117.

4. STORING AND HANDLING

Drainfill and filter aggregates shall be stored and handled by methods that prevent segregation of particle sizes or contamination by mixing with other materials.

MATERIAL SPECIFICATION

522. AGGREGATES FOR PORTLAND CEMENT CONCRETE

1. SCOPE

This specification covers the quality of fine aggregate and coarse aggregate for use in the manufacture of portland cement concrete.

2. QUALITY

Aggregate shall conform to the requirements of ASTM Specification C 33 for the specified sizes. Aggregates that fail to meet any requirement may be accepted only when: (1) the specified alternate conditions of acceptance can be proven prior to the use of the aggregates on the job and within a period of time such that no work under the contract will be delayed by the requirements of such proof; or, (2) the specification for concrete expressly contains a provision of special mix requirements to compensate for the effects of the deficiencies.

3. REACTIVITY WITH ALKALIES

The potential reactivity of aggregates with the alkalis in cement shall be evaluated by petrographic examination and, where applicable, the chemical method of test, ASTM Designation C 289, or by the results of previous tests or service records of concrete made from similar aggregates from the same source. The standards for evaluating potential reactivity shall be as described in ASTM Specification C 33, Appendix A1.

Aggregates indicated by any of the above to be potentially reactive shall not be used, except under one of the following conditions:

- a. Applicable test results of mortar bar tests, made according to ASTM Method C 227, are available which indicate an expansion of less than 0.10 percent at six (6) months in mortar bars made with cement containing not less than 0.8 percent alkalis expressed as sodium oxide; or
- b. Concrete made from similar aggregates from the same source has been demonstrated to be sound after three (3) years or more of service under conditions of exposure to moisture and weather similar to those anticipated for the concrete under these specifications.

Aggregates indicated to be potentially reactive, but within acceptable limits as determined by mortar bar test results or service records, shall be used only with "low alkali" cement, containing less than 0.60 percent alkalis expressed as sodium oxide.

4. STORING AND HANDLING

Aggregates of each class and size shall be stored and handled by methods that prevent segregation of particle sizes or contamination by intermixing with other materials.

MATERIAL SPECIFICATION

523. ROCK FOR RIPRAP

1. SCOPE

This specification covers the quality of rock to be used in the construction of rock riprap.

2. QUALITY

Individual rock fragments shall be dense, sound and free from cracks, seams and other defects conducive to accelerated weathering. Except as otherwise specified, the rock fragments shall be angular to subrounded in shape. The least dimension of an individual rock fragment shall be not less than one-third the greatest dimension of the fragment. ASTM D 4992 provides guidance on selecting rock from a source.

Except as otherwise provided, the rock shall be tested and shall have the following properties:

a. Rock Type 1

- (1) Bulk Specific Gravity (saturated surface-dry basis). Not less than 2.5 when tested in accordance with ASTM C 127 on samples prepared as described for soundness testing.
- (2) Absorption. Not more than 2 percent when tested in accordance with ASTM C 127 on samples prepared as described for soundness testing.
- (3) Soundness. The weight loss in five (5) cycles shall not be more than ten (10) percent when sodium sulfate is used or more than fifteen (15) percent when magnesium sulfate is used.

b. Rock Type 2

- (1) Bulk Specific Gravity (saturated surface-dry basis). Not less than 2.5 when tested in accordance with ASTM C 127 on samples prepared as described for soundness testing.
- (2) Absorption. Not more than 2 percent when tested in accordance with ASTM C 127 on samples prepared as described for soundness testing.
- (3) Soundness. The weight loss in five (5) cycles shall be not more than twenty (20) percent when sodium sulfate is used or more than twenty-five (25) percent when magnesium sulfate is used.

c. Rock Type 3

- (1) Bulk Specific Gravity (saturated surface-dry basis). Not less than 2.3 when tested in accordance with ASTM C 127 on samples prepared as described for soundness testing.

(2) Absorption. Not more than 4 percent when tested in accordance with ASTM C 127 on samples prepared as described for soundness testing.

(3) Soundness. The weight loss in five (5) cycles shall be not less than twenty (20) percent when sodium sulfate is used or more than twenty-five (25) percent when magnesium sulfate is used.

3. METHODS OF SOUNDNESS TESTING

- a. Rock Cube Soundness. The sodium or magnesium sulfate soundness test for all rock Types (1, 2, or 3) shall be performed on a test sample of 5000 ± 300 grams of rock fragments, reasonably uniform in size and cubical in shape and weighing, after sampling, approximately 100 grams each. They shall be obtained from rock samples that are representative of the total rock mass, as noted in ASTM D 4992, and that have been sawed into slabs as described in ASTM D 5121. The samples shall further be reduced in size by sawing the slabs into cubical blocks. The thickness of the slabs and the size of the sawed fragments shall be determined by the size of the available test apparatus and as necessary to provide, after sawing, the approximate 100 gram samples. The cubes shall undergo five cycles of soundness testing in accordance with ASTM C 88.

Internal defects may cause some of the cubes to break during the sawing process or during the initial soaking period. Do not test any of the cubes that break during this preparatory process. Such breakage, including an approximation of the percentage of cubes that break, shall be noted in the test report.

After the sample has been dried, following completion of the final test cycle and washed to remove the sodium sulfate or magnesium sulfate, the loss of weight shall be determined by subtracting from the original weight of the sample the final weight of all fragments that have not broken into three or more fragments.

The test report shall show the percentage loss of the weight and the results of the qualitative examination.

- b. Rock Slab Soundness. When specified, the rock shall also be tested in accordance with ASTM D 5240. Deterioration of more than 25 percent of the number of blocks shall be cause for rejection of rock from this source. Rock shall also meet the requirements for average percent weight loss stated below.

(1) For projects located north of the Number 20 Freeze-Thaw Severity Index Isoline (Map below approximates the map located in ASTM D 5312): Unless otherwise specified, the average percent weight loss for Rock Type 1 shall not exceed 20 percent when sodium sulfate is used or 25 percent when magnesium sulfate is used, and for Rock Types 2 and 3, the average percent weight loss shall not exceed 25 percent for sodium sulfate soundness or 30 percent for magnesium sulfate soundness.

(2) For projects located south of the Number 20 Freeze-Thaw Severity Index Isoline, unless otherwise specified, the average percent weight loss for Rock Type 1 shall not exceed 30 percent when sodium sulfate is used or 38 percent when magnesium sulfate is used, and for Rock Types 2 and 3, the average percent weight loss shall not exceed 38 percent for sodium sulfate soundness or 45 percent for magnesium sulfate soundness.

Map of the Conterminous United States
Showing the Number 20
Freeze-Thaw Severity Index Isoline

Adapted from ASTM D 5312

4. FIELD DURABILITY INSPECTION

Rock that fails to meet the material requirements stated above in a, b, or c (if specified), may be accepted only if similar rock from the same source has been demonstrated to be sound after five (5) years or more of service under conditions of weather, wetting and drying, and erosive forces similar to those anticipated for the rock to be installed under this specification.

A rock source may be rejected if the rock from that source deteriorates in three (3) to five (5) years under similar use and exposure conditions expected for the rock to be installed under this specification, even though it meets the testing requirements stated above.

Deterioration is defined as the loss of more than one-quarter (1/4) of the original rock volume, or severe cracking that would cause a block to split. Measurements of deterioration are taken from linear or surface area particle counts to determine the percentage of deteriorated blocks. Deterioration of more than 25 percent of the blocks shall be cause for rejection of rock from the source.

5. GRADING

The rock shall conform to the specified grading limits after it has been placed within the matrix of the rock riprap.

MATERIAL SPECIFICATION

531. PORTLAND CEMENT

1. SCOPE

This specification covers the quality of portland cement.

2. QUALITY

Portland cement shall conform to the requirements of ASTM Specification C 150 for the specific types of cement. When Type I portland cement is specified, Type IS portland blast-furnace slag cement or Type IP portland-pozzolan cement conforming to the requirements of ASTM Specification C 595 may be used unless prohibited by the specifications.

When air-entraining cement is required, the Contractor shall furnish the manufacturers written statement providing the source, amount and brand name of the air-entraining component.

3. STORAGE AT THE CONSTRUCTION SITE

Cement shall be stored and protected at all times from weather, dampness or other destructive elements. Cement that is partially hydrated or otherwise damaged will not be accepted.

MATERIAL SPECIFICATION

532. MINERAL ADMIXTURES FOR CONCRETE

1. SCOPE

This specification covers the quality of mineral admixtures for concrete.

2. QUALITY

Fly ash used as a partial substitution of portland cement shall conform to the requirements of ASTM C 618, Class C or F except the loss on ignition shall not exceed three (3) percent, unless otherwise specified. Lot-to-lot variation in the loss on ignition shall not exceed one (1) percent.

Blast-furnace slag used as a partial substitution of portland cement shall conform to ASTM Standard C 989 for ground granulated blast-furnace slag.

MATERIAL SPECIFICATION

533. CHEMICAL ADMIXTURES FOR CONCRETE

1. SCOPE

This specification covers the quality of chemical admixtures for manufacturer of portland cement concrete.

2. QUALITY

Air-entraining admixtures shall conform to the requirements of ASTM Specification C 260.

Water reducing and/or retarding admixtures shall conform to the requirements of ASTM Specification C 494, Types A, B, D, F, or G.

Plasticizing or plasticizing and retarding admixtures shall conform to ASTM Specification C 1017.

Accelerating or water-reducing and accelerating admixtures shall be non-corrosive and conform to the requirements of ASTM Specification C 494, Types C and E. The manufacturer shall provide long-term test data results from an independent laboratory verifying that the product is non-corrosive when used in concrete exposed to continuously moist conditions.

MATERIAL SPECIFICATION

534. CONCRETE CURING COMPOUND

1. SCOPE

This specification covers the quality of liquid membrane-forming compounds suitable for spraying on concrete surfaces to retard the loss of water during the concrete curing process.

2. QUALITY

The curing compound shall meet the requirements of ASTM Specification C 309.

Unless otherwise specified, the compound shall be Type 2.

3. DELIVERY AND STORAGE

All curing compound shall be delivered to the site of the work in the original container bearing the name of the manufacturer and the brand name. The compound shall be stored in a manner that prevents damage to the container and protects water-emulsion types from freezing.

MATERIAL SPECIFICATION

535. PREFORMED EXPANSION JOINT FILLER

1. SCOPE

This specification covers the quality of preformed expansion joint fillers for concrete.

2. QUALITY

Preformed expansion joint filler shall conform to the requirements of ASTM Specification D 1752, Type I, Type II, or Type III, unless bituminous type is specified. Bituminous type preformed expansion joint filler shall conform to the requirements of ASTM Specification D 994, or D 1751.

MATERIAL SPECIFICATION

536. SEALING COMPOUND FOR JOINTS IN CONCRETE AND CONCRETE PIPE

1. SCOPE

This specification covers the quality of sealing compound for filling joints in concrete pipe and concrete structures.

2. TYPE

The compound shall be a cold-application material, unless otherwise specified, and shall be a single component or multiple component type.

3. QUALITY

The sealing compound shall conform to the requirements of one of the following specifications:

ASTM Specification C 990; Joints for Concrete Pipe, Manholes, and Pre-cast Box Sections using Pre-formed Flexible Joint Sealants.

ASTM Specification C 877; External Sealing Bands for Non-Circular Concrete Sewer, Storm Drain, and Culvert Pipe.

ASTM Specification D 1190; Concrete Joint Sealer, Hot Poured Elastic Type.

ASTM Specification C 920; Elastomeric Joint Sealants for cold applied sealing and caulking of joints on mortar and concrete structures not subject to fuel spills. Use Type S or M, Grade NS for vertical joints; Type S or M, Grade P or NS for horizontal joints. Class 25, Use M, quality materials shall be used for both vertical and horizontal joints unless otherwise specified.

The sealing compound, if used with other joint materials, such as fillers or gaskets, shall be compatible.

MATERIAL SPECIFICATION

537. NON-METALLIC WATERSTOPS

1. SCOPE

This specification covers non-metallic waterstops for use in joints of concrete structures.

2. CLASSIFICATION

- a. Classes. Non-metallic waterstops shall be of the following classes, as specified:

Class I shall be fabricated of either natural or synthetic rubber.

Class II shall be fabricated of vinyl chloride polymer or copolymer.

- b. Types. Non-metallic waterstops may be either split or solid and shall conform to the following types, as specified, (see figure 1):

Type A shall have ribbed anchor flanges and a smooth web. Flanges may be of uniform thickness or may have either a converging or a diverging taper toward the edges.

Type B shall have ribbed anchor flanges and a smooth web containing a hollow tubular center bulb having: (1) a wall thickness equal to at least one-half (1/2) the web thickness, and; (2) the inside diameter (D) specified in the specifications or shown on the drawings. Flanges may be of uniform thickness or may have either a converging or a diverging taper toward the edges.

Type C shall have a single, circular bulb-type anchor flange at each edge and a smooth web.

Type D shall have a single, circular bulb-type anchor flange at each edge and a smooth web containing a hollow tubular center bulb having: (1) a wall thickness equal to a least one-half (1/2) the thickness of the web, and; (2) the inside diameter (D) specified in the contract.

Type E shall have ribbed anchor flanges and a web molded or extruded in the form of a round or U-shaped bulb of the dimensions specified in the contract or shown on the drawings. The web bulb shall be connected at the open-end of the "U" by a thin membrane having a minimum thickness of 1/64-inch and a maximum thickness of 1/5 of the web thickness and design to: (1) prevent infiltration of wet concrete into the bulb, and; (2) tear when expansion of the joint occurs. Flanges may be of uniform thickness or may have either a converging or a diverging taper toward the edges. Auxiliary positioning or nailing flanges may be provided as long as the functioning of the web bulb is not altered.

Type F shall have ribbed anchor flanges with a minimum of two (2) extra heavy ribs, designed to resist displacement of the waterstop during concrete placement

on each flange, and a smooth web having a positioning or nailing flange attached at the center.

Type G shall be of special design conforming to the details shown on the drawings.

- c. Sizes. Waterstops of Types A through F shall be of the sizes specified in the specifications or shown on the drawings and listed in Table 1 of this specification. Type G waterstops shall have the dimensions shown on the drawings.

3. PHYSICAL REQUIREMENTS

The extruded or molded materials shall exhibit the properties specified herein when tested by the methods specified in Section 4 of this specification.

a. Class I Waterstops

- (1) The hardness as determined by the Shore A durometer method shall be a minimum of 60.
- (2) The specific gravity shall be a maximum of 1.2.
- (3) The tensile strength shall be a minimum of 2500 pounds per square inch (psi).
- (4) The ultimate elongation shall be a minimum of 450 percent.
- (5) The compression set shall be a maximum of 30 percent.
- (6) The water absorption in weight measurements shall not exceed five (5) percent.
- (7) The decrease in tensile strength and ultimate elongation after aging shall not exceed 20 percent.
- (8) There shall be no sign of failure due to brittleness at a temperature of minus 35° F.

b. Class II Waterstops

- (1) The hardness as determined by the Shore A durometer method shall be a minimum of 60.
- (2) The specific gravity shall be a maximum of 1.4.
- (3) The tensile strength shall be a minimum of 1400 pounds per square inch (psi).

- (4) The ultimate elongation of the web shall be a minimum of 280 percent and the flanges shall be a minimum of 200 percent.
- (5) There shall be no sign of failure due to flange brittleness at a temperature of 0° F nor of web brittleness at a temperature of minus 35° F.
- (6) The decrease in either tensile strength or ultimate elongation after accelerated extraction shall not exceed 15 percent.
- (7) Results of alkali exposure:
 - (a) After immersion for seven (7) days, the sample shall exhibit no loss of weight and a maximum weight gain of 0.25 percent, and the hardness measured by the Shore A durometer method shall not vary more than 5 points either plus or minus from the untreated sample.
 - (b) After immersion for 30 days, the sample shall exhibit no loss of weight and a maximum weight gain of 0.40 percent, and the dimensions of the treated sample shall not vary by more than one (1) percent from the untreated sample.

4. TEST METHODS

Testing shall be conducted by the methods cited herein. All cited test methods are included in ASTM as follows:

- a. Hardness shall be determined by ASTM D 2240.
- b. Specific gravity shall be determined by ASTM D 792.
- c. Tensile strength shall be determined by ASTM D 412 for Class I waterstops and ASTM D 638 for Class II waterstops.
- d. Ultimate elongation shall be determined by ASTM D 412 for Class I waterstops and ASTM D 638 for Class II waterstops.
- e. Compression set shall be determined by ASTM D 395.
- f. Water absorption shall be determined by ASTM D 570.
- g. Tensile strength and ultimate elongation after aging shall be determined by ASTM D 412 for Class I waterstops and ASTM D 638 for Class II waterstops.
- h. Brittleness shall be determined by ASTM D 746 for Class II waterstops.
- i. Accelerated extraction shall be accomplished by procedures outlined by United States Army Corps of Engineers (USACE) Concrete Research Division (CRD) C 572 under the following conditions:

- (1) Samples shall not be less than 1/16 inch nor more than 1/8 inch in thickness;
 - (2) The immersion medium shall be a solution prepared by dissolving five (5) grams of chemically pure sodium hydroxide and five (5) grams of chemically pure potassium hydroxide in, one (1) liter of water;
 - (3) The samples shall be immersed in the medium for 14 days at a temperature of $145^{\circ} \text{F} \pm 5^{\circ} \text{F}$;
 - (4) During the period of immersion, air shall be gently bubbled through the medium from a 1/4 inch diameter glass tube at an approximate rate of one (1) bubble per second;
 - (5) Fresh medium shall be provided each day;
 - (6) Samples need not be dipped in acetone.
- j. The effects of alkalies shall be determined by USACE CRD C 572 under the following conditions:
- (1) Sample shall have a maximum thickness of 1/4 inch;
 - (2) The immersion medium shall be as described in (i) above;
 - (3) Fresh medium shall be provided every seven (7) days;
 - (4) The samples shall be immersed in the medium for a period of 30 days;
 - (5) Samples need not be dipped in acetone.

5. CONDITION

Waterstops shall be extruded or molded in such a manner that the material is dense and homogeneous throughout and free from voids, tears, thins, indentations, or other imperfections. Unless otherwise specified, waterstops shall be symmetrical in shape and uniform in dimensions and shall be furnished in continuous strips of minimum length of fifty (50) feet. Factory splices shall have a minimum tensile strength of fifty (50) percent of the unspliced section.

6. PACKAGING AND STORING

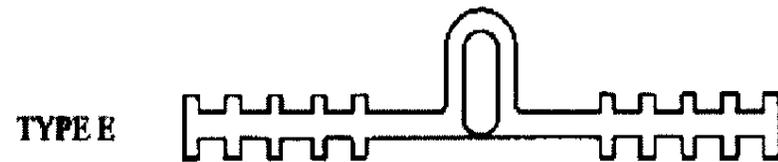

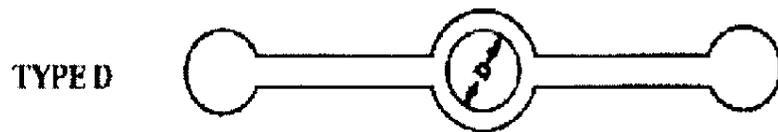

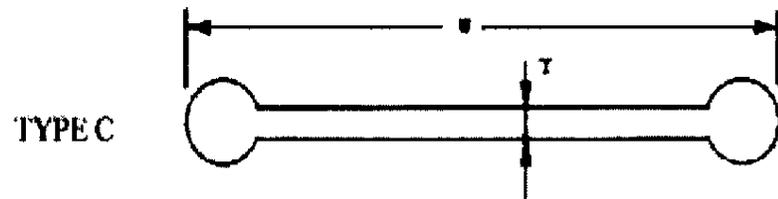

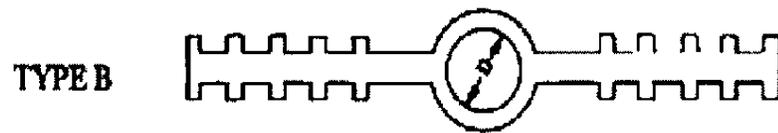

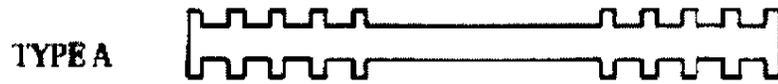

Waterstops shall be packaged and stored by methods that will provide protection from prolonged exposure to direct sunlight and/or excessive heat.

TABLE 1 SIZES OF WATERSTOPS

Size Designation	Web Thickness (T) Inches	Width (W) Inches
1	1/16	5 1/4
2	3/32	3 3/4
3	3/32	4
4	3/32	5 1/4
5	3/32	6
6	1/8	4
7	1/8	5 1/4
8	1/8	6
9	5/32	4
10	5/32	4 1/2
11	5/32	9
12	3/16	4
13	3/16	5
14	3/16	6
15	3/16	9
16	1/4	6
17	1/4	9
18	3/8	5
19	3/8	6
20	3/8	9
21	1/2	6
22	1/2	9
23	1/2	12

Figure 1

TYPES OF NON-METALLIC WATERSTOPS

MATERIAL SPECIFICATION

538. METAL WATERSTOPS

1. SCOPE

This specification covers the quality of materials for metal waterstops as specified for reinforced concrete installation.

2. MATERIALS

Metal waterstops shall be made of copper or galvanized steel as specified. Waterstops that require forming of the metal involving sharp bends shall be made of copper which shall be soft and pliable so bending to an inside radius equal to its thickness without cracking will occur at temperatures less than 180° F.

3. QUALITY

Metal for waterstops shall conform to the requirements of the applicable ASTM Standard below:

Copper - ASTM Specification B 152

Zinc-coated (Galvanized) steel - ASTM Specification A 653

MATERIAL SPECIFICATION

539. STEEL REINFORCEMENT (FOR CONCRETE)

1. SCOPE

This specification covers the quality of steel reinforcement for reinforced concrete.

2. QUALITY

All reinforcement shall be free from loose or flaky rust, soil, oil, grease, paint or other deleterious matter.

Steel bars for concrete reinforcement shall be Grade 40, 50, or 60 deformed bars conforming to one of the following specifications:

Deformed and Plain Billet-Steel Bars for Concrete Reinforcement - ASTM A 615

Rail-Steel Deformed and Plain Bars for Concrete Reinforcement - ASTM A 616 with the S1 supplemental requirements

Axle-Steel Deformed and Plain Bars for Concrete Reinforcement - ASTM A 617.

Dowels shall be plain round bars conforming to the same specifications listed above for steel bars.

Fabricated deformed steel bar mats for concrete reinforcement shall conform to the requirements of ASTM A 184.

Plain steel welded wire fabric for concrete reinforcement shall conform to the requirements of ASTM A 185.

Deformed steel welded wire fabric for concrete reinforcement shall conform to the requirements of ASTM A 497.

Epoxy-coated steel bars for concrete reinforcement shall conform to the requirements of ASTM A 775.

3. DIMENSIONS OF WELDED WIRE FABRIC

Gauges, diameters, spacing and arrangement of wires for welded steel wire fabric shall be as defined for the specified style designations.

4. STORAGE

Steel reinforcement inventories at the site of the work shall be stored above the ground surface on platforms, skids or other supports and shall be kept clean and protected from mechanical injury and corrosion.

MATERIAL SPECIFICATION

541. REINFORCED CONCRETE PRESSURE PIPE

1. SCOPE

This specification covers the quality of reinforced concrete pressure pipe and fittings.

2. MANUFACTURE AND FABRICATION

The pipe, the materials used in its manufacture, and the methods of fabrication shall conform to the requirements of the following specifications applicable to the specified type of pipe.

- a. Steel Cylinder Type, Pre-stressed: AWWA Standard C301 for Pre-stressed Concrete Pressure Pipe, Steel Cylinder Type, for Water and Other Liquids.
- b. Steel Cylinder Type, Not Pre-stressed: AWWA Standard C300 for Reinforced Concrete Pressure Pipe, Steel Cylinder Type, for Water and Other Liquids.
- c. Non-cylinder Type, Not Pre-stressed: AWWA Standard C302 for Reinforced Concrete Pressure Pipe, Non-cylinder Type, for Water and Other Liquids.
- d. Steel Cylinder Type, Pre-tensioned: AWWA Standard C303 for Concrete Pressure Pipe, Bar-Wrapped, Steel Cylinder Type for Water and Other Liquids.
- e. Low Head Pressure Pipe: ASTM Specification C 361. The following Specification Sections shall not apply:
 - AWWA C300 and C301, Sections 1.5 and 1.6.
 - AWWA C302 and C303, Sections 4.2 and 4.3.

3. DESIGN

The actual pipe and fittings shall be designed by the manufacturer to withstand the specified external loads and internal pressures. Designs shall be by either of the following methods as applicable to the type of pipe specified:

- a. Indirect Design: ASTM C497 for Standard Test Method for Concrete Pipe, Manhole Sections, or Tile.

Pipe design shall be based on the results of external crushing strength tests on a minimum two-foot length of the pipe or a specimen of equivalent size, design, and materials. The test shall demonstrate the following bearing loads:

- (1) For pipe manufactured according to ASTM C361, AWWA C300, or AWWA C302, the load required to produce a 0.01-inch crack on foot long.
- (2) For pipe manufactured according to ASTM C301, the load required to produce a 0.001-inch crack one foot long that is 10-percent greater than the specified three-edge bearing strength, whichever is lower.

In lieu of actual testing for this contract, pipe design may be based on Design Curve previously approved and published by the Natural Resources Conservation Service (formerly the Soil Conservation Service).

- b. Direct Design: AWWA C304 for Design of Pre-stressed Concrete Cylinder Pipe or AWWA Manual M9 for Concrete Pressure Pipe.

Pipe design shall be based on structural analysis and design calculations.

- c. Standard Design: ASTM C361 for Reinforced Concrete Low Head Pressure Pipe.

Pipe design shall be as published in the standard.

4. STEEL REINFORCEMENT

The steel reinforcements shall conform to the requirements of the specifications cited in Section 2 for the specified type of pipe, except that elliptical reinforcing cages or other reinforcements that require special orientation of the pipe during placement will not be allowed.

5. JOINTS

The pipe joints shall conform to the requirements of the applicable specification for the pipe. They shall be bell-and-spigot type or double-spigot-and-sleeve type and shall have a positive groove in the spigot to contain the rubber gasket. The size and shape of the groove shall be such that it will prevent displacement of the gasket by either internal or external water pressure when the joint is in any position within the required range of movement capability. Joint sleeves, also referred to as "collars" or "coupling bands," shall conform to the requirements for bell rings in the applicable pipe specification.

The joints shall be constructed so as to permit relative movement of the adjoining pipe sections with no reduction of watertightness. The joint length and the limiting angle defining the required capability of relative movement at each joint shall be no less than specified.

Joint length refers to the permissible axial movement in the joint, and is defined as the maximum distance through which the spigot can move, relative to the bell or sleeve, from the fully engaged to the fully extended condition of the joint when the adjoining pipe sections are in parallel, concentric alignment. The joint is considered to be fully engaged when the spigot is inserted as far as it will go into the bell or sleeve, and fully extended when it is inserted the least amount that will ensure full confinement of the gasket and complete watertightness.

Joint length specified for double-spigot joints refers to the permissible movement in each of the spigot-to-sleeve connections, not the sum of the two.

The limiting angle of the joint is defined as the maximum deflection angle between adjoining pipe sections the joint will permit before the outer surface of the spigot comes into direct contact with inside of the mating bell or sleeve. If both spigot-to-sleeve connections of a double-spigot joint permit angular movement, the limiting angle of the joint is the sum of the two deflection angles permitted by the two connections.

6. GASKETS

The pipe joint gaskets shall conform to the requirements of the specifications cited in Section 2 of this specification. They shall be endless rubber gaskets having circular cross section. The cross-sectional diameter of the gaskets shall conform to the pipe manufacturer's recommendation for the type and size of pipe furnished.

7. MARKING

All pipe sections and special fittings shall be marked by the manufacturer with the manufacturer's name or trademark, the date of manufacture, the nominal size, design head, design external load and the structure site for which it was designed and manufactured.

8. CERTIFICATION

All component materials and actual pipe fabrication shall be tested, inspected, and documented as prescribed in the manufacturing specifications for the type of pipe specified. All documentation noted in the manufacturing specifications shall be submitted to the Engineer. Documentation shall include current test reports on steel and steel wire reinforcing and compression tests of concrete used in the manufacture of the furnished pipe.

For pipe design based on actual external crushing strength tests, the Engineer shall witness the actual test.

For pipe design based on published Design Curves, a copy of the appropriate design curve marked to show the resultant concrete core stress and corresponding three-edge bearing load, and a specification sheet showing all data and dimensions necessary to calculate the resultant core stress, for the pipe furnished shall be submitted to the Engineer.

For pipe design based on structural analysis and calculations, such analysis and calculations shall be submitted to the Engineer. Printouts of such calculations by computer programs shall be sufficiently detailed to enable comparison with standardized procedures and methods.

Drawings, details, and descriptions of the pipe joints as necessary to show that the joint conforms to the specified requirements shall also be submitted.

MATERIAL SPECIFICATION

542. CONCRETE CULVERT PIPE

1. SCOPE

This specification covers the quality of non-reinforced and reinforced concrete culvert pipe.

2. NON-REINFORCED PIPE

Non-reinforced concrete culvert pipe shall conform to the requirements of ASTM Specification C 14 for the class of pipe specified.

3. REINFORCED PIPE

- a. Round pipe. Round reinforced concrete culvert pipe shall conform to the requirements of ASTM Specification C 76 or ASTM C 655 for the class of pipe specified.
- b. Arch pipe. Reinforced concrete arch culvert pipe shall conform to the requirements of ASTM Specifications C 506 for the class of pipe specified.
- c. Elliptical pipe. Reinforced concrete elliptical culvert pipe shall conform to the requirements of ASTM Specification C 507 for the class of pipe specified.

4. REINFORCED BOX SECTIONS

Reinforced concrete box sections shall be manufactured meeting the requirements of ASTM Specifications C 789 or C 850 based on the design specified.

5. RUBBER GASKET JOINTS

When rubber gasket joints are specified, the joints and gaskets shall conform to the requirements of ASTM Specification C 443.

MATERIAL SPECIFICATION

543. NON-REINFORCED CONCRETE PIPE

1. SCOPE

This specification covers the quality of non-reinforced concrete irrigation pipe, drainage pipe, and drain tile.

2. IRRIGATION PIPE

Unless rubber gasket joints are specified, non-reinforced concrete irrigation pipe shall conform to the requirements of ASTM Specification C 118 for Standard Concrete Irrigation Pipe.

3. IRRIGATION PIPE WITH RUBBER GASKET JOINTS

Non-reinforced concrete irrigation pipe with rubber gasket joints shall conform to the requirements of ASTM Specification C 505.

4. DRAINAGE PIPE

Non-reinforced concrete drainage pipe shall conform to the requirements of ASTM Specification C 118 for the class of pipe specified.

5. PERFORATED PIPE

Perforated non-reinforced concrete pipe shall conform to the requirements of ASTM Specification C 444 for the class of pipe specified.

6. DRAIN TILE

Concrete drain tile shall conform to the requirements of ASTM Specification C 412 for the class of tile specified.

MATERIAL SPECIFICATION

544. CLAY PIPE AND DRAIN TILE

1. SCOPE

This specification covers the quality of clay pipe and drain tile.

2. PIPE

Standard strength clay pipe and extra strength clay pipe shall conform to the requirements of ASTM Specification C 700 for the specified class of pipe.

3. PERFORATED PIPE

Perforated clay pipe shall conform to the requirements of ASTM Specification C 700 for the specified class of pipe.

4. DRAIN TILE

Clay drain tile shall conform to the requirements of ASTM Specification C 4 for the specified class of tile. Perforated drain tile shall conform to the requirements of ASTM Specification C 498 for the specified class.

5. COMPRESSION JOINT MATERIAL

Compression joints using material having resilient properties shall conform to the requirements of ASTM Specification C 425.

MATERIAL SPECIFICATION

547. PLASTIC PIPE

1. SCOPE

This specification covers the quality of Poly Vinyl Chloride (PVC), Polyethylene (PE), High Density Polyethylene (HDPE), and Acrylonitrile-Butadiene-Styrene (ABS) plastic pipe, fittings and joint materials.

2. MATERIALS

a. Pipe

The pipe shall be as uniform as commercially practicable in color, opaqueness, density, and other specified physical properties and free from visible cracks, holes, foreign inclusions, or other defects. The dimensions of the pipe shall be measured as prescribed in ASTM D 2122.

Unless otherwise specified, the pipe shall conform to the requirements listed in this specification and the applicable reference specifications in Table 547-2, the requirements specified in Construction Specification [45, Plastic Pipe](#), and the requirements shown on the drawings.

b. Fittings and Joints

Fittings and joints shall be of a schedule, SDR or DR, pressure class, external load carrying capacity, or pipe stiffness that equals or exceeds that of the plastic pipe. The dimensions of fittings and joints shall be compatible with the pipe and measured in accordance with ASTM D 2122. Joint and fitting material shall be compatible with the pipe material. The joints and fittings shall be as uniform as commercially practicable in color, opaqueness, density, and other specified physical properties and free from visible cracks, holes, foreign inclusions, or other defects.

Fittings and joints shall conform to the requirements listed in this specification, the requirements of the applicable specification referenced in the ASTM or AWWA specification for the pipe, the requirements specified in Construction Specification 45, and the requirements shown on the drawings.

c. Solvents

Solvents for solvent welded pipe joints shall be compatible with the plastic pipe used and shall conform to the requirements of the applicable specification referenced in the ASTM or AWWA specification for the pipe, fitting, or joint.

d. Gaskets

Rubber gaskets for pipe joints shall conform to the requirements of ASTM F 477, Elastomeric Seals (Gaskets) for Jointing-Plastic Pipe.

3. PERFORATIONS

When perforated pipe is specified, perforations shall conform to the following requirements, unless otherwise specified in Construction Specification 45 or shown on the drawings:

- a. Perforations shall be either circular or slots.
- b. Circular perforations shall be $1/4 \pm 1/16$ -inch diameter holes arranged in rows parallel to the axis of the pipe. Perforations shall be evenly spaced along each row such that the center-to-center distance between perforations is not less than eight (8) times the perforation diameter. Perforations may appear at the ends of short and random lengths. The minimum perforation opening per foot of pipe shall be as shown in Table 547-1.

Rows shall be arranged in two (2) equal groups at equal distance from the bottom on each side of the vertical centerline of the pipe. The lowermost rows of perforations shall be separated by an arc of not less than 60° or more than 125° . The uppermost rows of perforations shall be separated by an arc not to exceed 166° . The spacing of rows between these limits shall be uniform. The minimum number of rows shall be as shown in Table 547-1.

- c. Slot perforations shall be symmetrically located in two (2) rows, one on each side of the pipe centerline. Slot perforations shall be located within the lower quadrants of the pipe with slots no wider than $1/8$ inch and spaced not to exceed 11 times the perforation width. Minimum perforation opening per lineal foot of pipe shall be as shown in Table 547-1.

TABLE 547-1
PERFORATIONS

NOMINAL PIPE SIZE	MINIMUM NUMBER OF ROWS		MINIMUM OPENING/FOOT
	(Inches)	CIRCULAR	SLOT
4	2	2	0.22
6	4	2	0.44
8	4	2	0.44
10	4	2	0.44
12	6	2	0.66

- d. On both the inside and outside of the pipe, perforations shall be free of cuttings or frayed edges, and any materials that would reduce the effective opening.

MATERIAL SPECIFICATION

548. CORRUGATED POLYETHYLENE TUBING

1. SCOPE

The specification covers the quality of corrugated polyethylene tubing and fittings.

2. TUBING

Corrugated polyethylene tubing shall conform to the requirements of ASTM F 405, ASTM F 667, ASTM F 894, AASHTO M 252, or AASHTO M 294 for the appropriate tubing sizes and fittings.

3. FITTINGS

ASTM F 405	3 - 6 inch diameter pipe and fittings
ASTM F 667	8, 10, 12, 15, 18, and 24 inch diameter pipe and fittings
ASTM F 894	18 - 120 inch diameter pipe and fittings
AASHTO M 252	3 - 10 inch diameter N12 pipe and fittings
AASHTO M 294	12 - 36 inch diameter N12 pipe and fittings

MATERIAL SPECIFICATION

551. COATED CORRUGATED STEEL PIPE

1. SCOPE

This specification covers the quality of zinc-coated, aluminum-coated, aluminum-zinc alloy-coated, and polymer-coated corrugated steel pipe and fittings.

2. PIPE

All pipe shall be metallic zinc-coated, aluminum-coated, or aluminum-zinc alloy-coated corrugated steel pipe and fittings conforming to the requirements of ASTM A 742, A 760, A 761, A 762, A 849, A 875, A 885, and A 929 for the specified type, class, fabrication of pipe and coating, and to the following additional requirements:

a. When closed riveted pipe is specified:

(1) Pipe shall be fabricated with circumferential seam rivet spacing that does not exceed three (3) inches, except that twelve (12) rivets will be sufficient to secure the circumferential seams in twelve (12) inch pipe.

and,

(2) Longitudinal seams that will be within the coverage area of a coupling band, the rivets shall have flat heads or the rivets and holes shall be omitted and the seams shall be connected by welding to provide a minimum of obstruction to the seating of the coupling bands.

b. Double riveting or double spot welding for pipe less than 42 inches in diameter may be required. When double riveting or double spot welding is specified, the riveting or welding shall be performed in a manner specified for pipe 42 inches or greater in diameter.

3. COATINGS

Coatings described herein, unless otherwise specified, refer to equally both the inside and outside pipe surfaces.

When coatings in addition to metallic coatings are specified, they shall conform to the requirements of ASTM A 742, A 760, A 761, A 762, A 849, A 875, A 885, and A 929 for the specified type.

Polymer-coated pipe, unless otherwise specified on the drawings or in the construction specifications, shall be coated on each side with a minimum thickness of 0.01 inches (10 mils), designated as grade 10/10 in ASTM A 762.

4. COUPLING BANDS

Coupling bands are to be provided for each section of pipe. The hardware for fastening the coupling band tightly to the connecting pipe shall be fabricated to

permit tightening sufficiently to provide the required joint tensile strength and, if required, watertightness without failure of its fastening.

Gaskets, if specified, are to be provided for each coupling band. The fabrication of coupling bands and fastening hardware, in addition to the above, shall be sufficient to provide the required gasket seating without warping, twisting or bending.

5. FITTINGS

Fittings shall be fabricated from steel conforming to ASTM A 444, A 742, A 806, A 819, A 849, A 875, A 885, and A 929. The coating of fittings shall be the same as that specified for the contiguous corrugated coated pipe.

Welded surfaces and adjacent surfaces damaged during welding shall be treated by removal of all flux residue and weld splatter. The affected surfaces shall be cleaned to bright metal by sand blasting, power disk sanding, or wire brushing. The cleaned area shall extend a minimum of one-half (1/2) inch into the undamaged section of the coated area. Repair and coating application of damaged and uncoated pipe surface areas shall be in accordance with ASTM A 780.

MATERIAL SPECIFICATION

552. ALUMINUM CORRUGATED PIPE

1. SCOPE

This specification covers the quality of aluminum corrugated pipe and fittings.

2. PIPE

Aluminum corrugated pipe and fittings shall conform to the requirements of ASTM B 745, B 746, or B 790 for the specified pipe sheet thickness, shape type, fabrication methods, and the following additional requirements:

a. When close-ribbed pipe is specified:

(1) Pipe shall be fabricated with circumferential seam rivet spacing that does not exceed three (3) inches, except that twelve (12) rivets will be sufficient to secure the circumferential seams in twelve (12) inch pipe.

and,

(2) Longitudinal seams that will be within the coverage area of a coupling band, the rivets shall have flat heads or the rivets and holes shall be omitted and the seams shall be connected by welding to provide a minimum of obstruction to the seating of the coupling bands.

3. COATINGS

Bituminous coatings, when specified, shall conform to the requirements of ASTM A 849.

4. COUPLING BANDS

Coupling bands are to be provided for each section of pipe. The hardware for fastening the coupling band tightly to the connecting pipe shall be fabricated to permit tightening sufficiently to provide the required joint tensile strength and, if required, watertightness without failure of its fastening.

Gaskets, if specified, are to be provided for each coupling band. The fabrication shall also be sufficient to provide the required gasket seating without warping, twisting or bending.

Gaskets provided with connecting bands meeting requirements for special joints in erodible soil conditions shall be as specified in ASTM A 762.

5. FITTINGS

Fittings shall be fabricated from sheet aluminum meeting the requirements contained in ASTM B 744. The coating for fittings shall be the same as that specified for the contiguous corrugated aluminum pipe.

Fittings that are welded during fabrication shall be accomplished in a good workmanship like manner resulting in a continuous smooth surface finish. Aluminum welding electrodes used shall conform to the requirements of American Welding Society (AWS) specification AWS A5.10, "Specification for Aluminum and Aluminum Alloy Welding Rods and Bare Electrodes." Welded surfaces and adjacent surfaces damaged during welding shall be treated by removal of all weld splatter. The affected surface shall be cleaned to bright metal by sand blasting, power disk sanding, or wire brushing. The cleaned area shall extend a minimum of one-half (1/2) inch into the undamaged section of coated area. Within 24 hours of completion of surface preparation all treated surfaces shall be painted with two (2) coats of a chromate rich primer and allowed to fully dry prior to exposure to weathering conditions.

Aluminum surfaces fabricated that will have contact with steel, iron, or other metals shall be coated with a zinc-chromate primer and allowed to fully dry prior to final installation.

MATERIAL SPECIFICATION

553. DUCTILE-IRON PIPE

1. SCOPE

This specification covers the quality of ductile-iron pipe and fittings.

2. PIPE

Ductile-Iron Pipe shall conform to the requirements of ANSI/AWWA C151/A21.51, Ductile-Iron Pipe, Centrifugally Cast in Metal Molds or Sand-Lined Molds for Water or Other Liquids and ANSI/AWWA C115/A21.15, Flanged Ductile-Iron Pipe with Threaded Flanges.

3. FITTINGS

Ductile-Iron Pipe Fittings shall conform to the requirements of ANSI/AWWA C110/A21.10, Ductile-Iron and Gray-Iron Fittings, 3-inch through 48-inch, for Water and Other Liquids. Also, ANSI/AWWA C153/A21.53, Ductile-Iron Compact Fittings, 3-inch through 12-inch, for Water and Other Liquids.

4. JOINTS

Rubber-gasket joints for ductile-iron pipe and fittings where either mechanical or push-on joints are used shall conform to the requirements of ANSI/AWWA C111/A21.11, Rubber-Gasket Joints for Ductile-Iron and Gray-Iron Pressure Pipe and Fittings.

5. LINING

Interior lining for Ductile-Iron Pipe and Fittings shall conform to the requirements of ANSI/AWWA C104/A21.4, Cement Mortar Lining for Ductile-Iron Pipe and Fittings for Water.

6. ENCASEMENT

Encasement for ductile-iron pipe and fittings shall conform to the requirements of ANSI/AWWA C105/A21.5-88, Polyethylene Encasement for Ductile-Iron Pipe for Water and Other Liquids.

MATERIAL SPECIFICATION

554. STEEL PIPE

1. SCOPE

This specification covers the quality of steel pipe and fittings.

2. PIPE

Steel pipe shall conform to the requirements of the applicable specification listed below for the kind of pipe and the type, weight, grade, and finish specified:

<u>Kinds of Pipe</u>	<u>ASTM Specification</u>
Pipe, Steel, Black and Hot-Dipped, Zinc-Coated Welded and Seamless	A 53
Pipe, Steel, Electric-Fusion (ARC) - Welded (Sizes NPS 16 and Over)	A 134
Electric-Resistance-Welded Steel Pipe	A 135
Electric-Fusion (ARC) - Welded Steel Pipe (NPS 4 and Over)	A 139
	<u>AWWA Standard</u>
Steel Water Pipe 6 Inches and Larger	C 200

3. FITTINGS

Fittings shall conform to the requirements for the types and kinds specified.

<u>Fittings</u>	<u>ASTM Specification</u>
Heat-Treated Carbon Steel Fittings for Low-Temperature and Corrosive Service	A 858
Threaded Couplings, Steel, Black or Zinc-Coated (Galvanized) Welded or Seamless, for Use in Steel Pipe Joints	A 865

MATERIAL SPECIFICATION

571. SLIDE GATES

1. SCOPE

This specification covers the quality of metal slide gates for water control.

2. CLASS AND TYPE OF GATE

The class of gate will be expressed as a numerical symbol composed of the seating head and unseating head. The two numbers will be separated by a hyphen with the seating head listed first. For this purpose, the heads shall be expressed in terms of feet of water.

Gates shall be of the specified types as defined below:

Light Duty:

Type MLS-1 gates shall be cast iron with cast iron seat facings.

Type MLS-2 gates shall be fabricated metal gates.

Moderate Duty:

Type MMS-1 gates shall be cast iron with bronze seat facings, cast iron or galvanized structural steel guides, and galvanized steel, bronze, or stainless steel fasteners.

Type MMS-2 gates shall be cast iron with bronze seat facings, cast iron or stainless steel guides, and bronze or stainless steel fasteners. Guides and fasteners shall be stainless steel, when specified.

Heavy Duty:

Type MHS-1 gates shall have gray cast iron slides, frames, guides and yokes and shall be fitted with: (1) bronze seat facings, bronze wedges and wedge blocks or wedge seat facings, and bronze stem blocks or thrust nuts, (2) bronze or stainless steel fasteners, and (3) cold rolled steel stems, except that stems shall be stainless steel where so specified.

Type MHS-2 gates shall have gray cast iron slides, frame, guides, and yokes and shall be fitted with: (1) Stainless steel seat facings, wedges, wedge seat facings, stems and fasteners, and (2) austenitic cast iron stem blocks or thrust nuts.

Type MHS-3 gates shall have austenitic gray cast iron slides, frames, guides, and yokes and shall be fitted with: (1) nickel-copper alloy seat facings, wedges, wedge seat facings, stems and fasteners, and (2) austenitic cast iron stem blocks or thrust nuts.

3. QUALITY OF MATERIALS

Materials for slide gates and appurtenances shall conform to the requirements of the applicable specifications listed below for the alloy, grade, type, or class of material and the condition and finish appropriate to the structural and operational requirements.

<u>Material</u>	<u>ASTM Specification</u>
Cast iron and Gray cast iron	A 48, Class 30, or A 126, Class B
Austenitic cast iron	A 436
Structural steel shapes, plates, and bars	A 36
Cold rolled steel	A 108
Carbon steel bars	A 108 or A 575
Stainless steel	A 167, A 276, or A 582 Type 302, 303, 304, or 304L
Castings, nickel and nickel alloy	A 494
Carbon steel sheets and strips	A 569
Zinc-coated carbon steel sheets	A 653 or A 924
Bronze bar, rods, shapes	B 21 or B 98
Naval bronze	B 21
Phosphor bronze	B 103 or B 139
Manganese bronze	B 138 or B 584
Silicon bronze	B 98 or B 584
Cast bronze	B 584
Nickel-copper alloy plate, sheet, strip	B 127
Nickel-copper alloy rod or bar	B 164
Rubber for gaskets and seals	D 2000

Galvanizing (zinc coating) shall conform to the requirements of Material Specification 582.

4. FABRICATED METAL GATES (LIGHT DUTY GATES)

Fabricated metal gates shall be built to withstand the seating head expressed by the gate class designation. Unless otherwise specified, the gates shall be galvanized steel with flat-back frames.

5. CAST IRON GATES (LIGHT DUTY GATES)

The frame shall be cast iron of the specified type. The front face shall be machined to receive the gate guides.

The gate slide shall be cast iron and shall be fabricated to withstand the seating and unseating heads expressed by the gate class designation as defined in Section 2 of this specification.

Grooves shall be cast on the vertical sides of the slide to match the guide angles.

The gates guides shall be galvanized structural steel and shall be fabricated to withstand the total thrust of the gate slide due to water pressure and wedge action under maximum operating conditions.

Wedges and wedge seats shall have smooth bearing surfaces. Wedges may be cast as integral parts of the slide. Removable wedges and wedge seats shall be fastened to the slide, frame or guides by means of suitable studs, screws, or bolts and shall be firmly locked in place after final adjustment. Each interacting set of wedge and wedge seat shall be adjustable as needed to insure accurate and effective contact. Adjusting bolts or screws shall be bronze or galvanized steel.

Seat facings shall be machined to a smooth finish to insure proper watertight contact.

6. FRAME OR SEAT (MODERATE AND HEAVY DUTY GATES)

The frame shall be cast iron and of the specified type. The front face shall be machined to receive the gates guides and the rear face shall be machined as required to match the specified attaching means. For heavy-duty gates, a dovetailed groove shall be machined on the perimeter of the front face to receive the seat facing.

7. GATE SLIDE (MODERATE AND HEAVY DUTY GATES)

The gate slide shall be cast iron, rectangular in shape and shall have horizontal and vertical stiffening ribs of sufficient section to withstand the seating and unseating heads expressed by the gate class designation as defined in Section 2 of this

specification. For heavy-duty gates, a dovetailed groove shall be machined on the perimeter of the slide face to receive the seat facing.

Tongues shall be machined on the vertical sides of the slide along its entire height to match the guide grooves and angles with a maximum clearance of 1/16 inch for gates smaller than 54 inches by 54 inches, and 1/8 inch for larger gates.

A nut pocket with reinforcing ribs shall be integrally cast on the vertical centerline and above the horizontal centerline of the slide. The pocket shall be of a shape adequate to receive a flat-backed thrust nut or stem block and shall be built to withstand the opening and closing thrust of the stem.

8. GATE GUIDES (MODERATE AND HEAVY DUTY GATES)

The gate guides shall be built to withstand the total thrust of the gate slide due to water pressure and wedge action. The gate guides shall be cast iron for heavy-duty gates.

Grooves shall be machine-in cast iron guides to receive the tongue on the gate slide throughout the entire length of the guide.

The guides shall be of adequate length to retain a minimum of one-half the height of the gate slide when the gate is fully opened.

9. WEDGES AND WEDGE SEATS (MODERATE AND HEAVY DUTY GATES)

Pads for supporting wedges, wedge seats (or blocks) and wedge loops (or stirrups) shall be cast as integral parts of the gate frame, slide, or guides and shall be accurately machined to receive those parts.

Wedges and wedge seats shall have smooth bearing surfaces for moderate duty gates and shall have machine finish bearing surfaces for heavy-duty gates. Removable wedges may be cast as integral part of the slide for moderate duty gates. Wedges shall be fastened to the gate slide, frame or guides by means of suitable studs, screws, or bolts and shall be firmly locked in place after final adjustment. Each interacting set of wedge and wedge seat shall be adjustable as needed to insure accurate and effective contact.

10. SEAT FACING

Moderate Duty Gates - Seat facings shall be machined to a smooth finish to insure proper watertight contact. Bronze facings shall be securely attached by welding or by other approved methods.

Heavy Duty Gates - Seat facings shall be pressed or impacted into the machined dove tailed grooves on the gate slide and frame and machined to a smooth finish to insure proper watertight contact.

11. YOKE

When a self-contained gate is specified, the yoke shall be of such design as to withstand the loads resulting from normal operation of the gate. For moderate and heavy duty gates, cast iron yokes shall be provided with machined pads for connecting to the ends of gates guides and to receive the stem thrust cap or handwheel lift.

12. FLUSH BOTTOM SEAL (HEAVY DUTY GATE)

When a flush bottom sealing gates is specified, a solid, square-corner type rubber seal shall be provided at the bottom of the gate opening. It shall be securely attached either to the bottom of the slide or to the frame. Metal surfaces bearing on the rubber seal shall be smooth and rounded as necessary to prevent cutting of the seal during gate operation.

13. GATE STEM AND LIFT (OR HOIST)

The gate stem and lift/hoist shall be of the specified type, size and capacity and, if hand operated, shall be capable of moving the gate slide under normal conditions, following unseating from the wedging device, with a pull on the handwheel or crank of not more than 25 pounds with the specified seating and/or unseating head of water against the gate.

Unless otherwise specified, the stem shall be carbon steel and shall be furnished in sections as necessary to permit reasonable ease in installation. Couplings shall be bolted, pinned, or keyed to the stem. The stem shall be furnished with rolled or machine-cut 29° Acme threads of sufficient length to completely open the gate. The threads shall be smooth and of uniform lead and cross-section, such that the nut can travel the full length without binding or excessive friction. For moderate and heavy-duty gates, the stem shall be threaded for connection to the stem block or thrust nut on the gate slide.

The lift shall be compatible with the type of stem furnished. Unless otherwise specified, the lift nut shall be cast bronze for light and moderate duty gates and cast manganese bronze for heavy duty gates and shall be fitted with ball or roller thrust bearings designed to withstand the normal thrust developed during opening and closing of the gate at the maximum operating heads. All gears, sprockets and pinions shall be machine-cut, with ratios and strength adequate to withstand expected operating loads. Sufficient grease fittings shall be provided to allow lubrication of all moving parts. An arrow and the word "open" shall be cast on the rim of the handwheel or on the lift housing to indicate the direction of gate opening. Unless otherwise specified, the lift for the non-rising-stem gate shall be provided with an indicator capable of showing both when the gate is fully open and when it is fully closed for the moderate and heavy-duty gates.

Provisions shall be made to prevent stem rotation within the stem block or thrust nut or at the connection the gate slide.

Stop collars shall be provided to prevent over-travel in opening and closing the gate.

14. STEM GUIDES

Unless otherwise specified, stem guides shall be cast iron for light duty gates and cast iron with bronze bushed collars for moderate and heavy-duty gates, and be fully adjustable in two directions.

15. WALL THIMBLE (MODERATE AND HEAVY DUTY GATES)

When a wall thimble is specified, it shall be of the same cast iron used in the gate frame and of the section, type, and depth specified. The front flange shall be machined to match the gate frame and drilled and tapped to accurately receive the gate attachment studs.

Gaskets or mastic to be installed between the thimble and the gate frame shall conform to the recommendations of the gate manufacturer and shall be furnished with the thimble.

16. FASTENERS

Unless otherwise specified, all anchor bolts and other fasteners shall be galvanized steel or bronze for light duty gates; galvanized steel or stainless steel or bronze for moderate duty gates; and, of the quality and size as recommended by the gate manufacturer for heavy duty gates. All anchor bolts, assembly bolts, screws, nuts, and other fasteners shall be of ample section to withstand the forces created by operation of the gate while subjected to the specified seating and unseating heads. Anchor bolts shall be furnished with two (2) nuts to facilitate installation.

17. INSTALLATION INSTRUCTIONS

Prior to installation, the Contractor shall provide to the Engineer the manufacturer's complete installation data, instructions for adjustments and drawings or templates showing the location of all anchor bolts for each gate.

18. PAINTING

When specified, gates and accessories shall be painted by the designated paint system.

19. CERTIFICATION

The supporting data submitted to the Engineer shall include the name of the manufacturer, the manufacturer's model number (for standard catalogue items) or the seating and unseating heads for which the gate is designed together with such drawings and specifications as may be necessary to show that the gate conforms to the requirements of this specification.

MATERIAL SPECIFICATION

572. FLAP GATES, METAL

1. SCOPE

This specification covers the quality of metal flap gates for water control.

2. CLASS AND TYPE OF GATE

The class of gate will be expressed as the numerical value of the seating head, which the gate must be built to withstand. For this purpose, the head shall be expressed in terms of feet of water measured to the center of the gate.

Gates shall be of the specified type as defined below:

Light Duty:

Type MLF-1 gates shall be cast iron or cast steel and shall be fitted with unbushed linkage systems and galvanized steel fasteners, or with bronze bushed linkage systems and bronze or stainless steel fasteners.

Moderate Duty:

Type MMF-1 gates shall be cast iron or cast steel and shall be fitted with bronze seat facings, bronze bushed linkage systems and bronze or stainless steel fasteners.

Heavy Duty:

Type MHF-1 gates shall have gray cast iron frames and flaps and shall be fitted with naval bronze seat facings, gray cast iron or high-strength bronze hinge arms, bronze bushings, bronze hinge pins, and bronze fasteners.

Type MHF-1R gates shall be the same as Type MHF-1 gates except that the frame shall be fitted with a rubber seat facing instead of a metal seat facing.

Type MHF-2 gates shall have gray cast iron frames and flaps and shall be fitted with stainless steel seat facings, gray cast iron or stainless steel hinge arms, and stainless steel bushings, hinge pins, and fasteners.

Type MHF-2R gates shall be the same as Type MHF-2 gates except that the frame shall be fitted with a rubber seat facing instead of a metal seat facing.

Type MHF-3 gates shall have austenitic gray cast iron frames, flaps and hinge arms and shall be fitted with nickel-copper alloy seat facings, bushings, hinge pins and fasteners.

Type MHF-3R gates shall be the same as Type MHF-3 except that the frame shall be fitted with a rubber seat facing instead of a metal seat facing.

3. QUALITY OF MATERIALS

Materials in flap gates and appurtenances shall conform to the requirements of the applicable specifications listed below for the alloy, grade, type, or class of material and the condition and finish appropriate to the structural and operational requirements:

<u>Materials</u>	<u>ASTM Specifications</u>
Cast iron and Gray cast iron	A 48, Class 30, or A 126, Class B
Cast Steel	A 27 or A 148
Structural steel shapes, plates, and bars	A 36
Carbon steel bars	A 108 or A 575
Stainless steel	A 167, A 276 or A 582 Type 302, 303, 304, or 304L
Austenitic gray cast iron	A 436
Castings, nickel and nickel-alloy	A 494
Carbon steel sheets & strips	A 569
Bronze bar, rods, shapes and Naval bronze	B 21 or B 98
Red Brass	B 43
Silicon bronze	B 98 or B 584
Phosphor bronze	B 103 or B 139
Manganese bronze	B 138 or B 584
Nickel-copper alloy plate, sheet, strip	B 127
Nickel-copper alloy rod, bar	B 164
Cast bronze	B 584
Rubber gaskets and seals	D 2000

4. FRAME

The frame shall be cast iron or cast steel for light and moderate duty gates and as specified for heavy-duty gates, and of the specified type. For moderate and heavy-duty gates, the rear face shall be machined as required to match the specified attaching means. For the heavy-duty gate, a groove shall be machined on the perimeter of the front face to receive the seat facing.

5. FLAP

For light and moderate duty gates, the flap shall be cast iron or cast steel and shall be built to withstand the seating head expressed by the gate class designation, as defined in Section 2 of this specification.

For heavy-duty gates, the flap shall be built to withstand the seating head expressed by the gate class designation, as defined in Section 2 of this specification. A groove shall be machined on the perimeter of the face to receive the seat facing.

6. LINKAGE SYSTEM

The linkage system by which the flap is mounted onto the frame shall be double-pivoted type for gates over eight (8) inches in diameter. It shall be designed to prevent the flap from folding inside of the seat and wedging in the open position. For the moderate heavy-duty gates, the top pivot shall be so designed as to allow adjustment of gate alignment and sensitivity.

7. SEAT FACINGS

Light Duty Gates - All facings shall be machined to a smooth finish to insure proper contact.

Moderate Duty Gates - Seat facings shall be securely attached by welding, or other approved means, and machined to a smooth finish to insure proper contact.

Heavy Duty Gates - Metal facings shall be pressed or impacted into machined dovetailed grooves on the flap and frame (or securely attached in the seat grooves by means of studs, set screws or other approved means) and machined to a smooth finish to insure proper contact. Rubber facings shall be pressed into a dovetailed groove in the frame.

8. WALL THIMBLE

For moderate and heavy-duty gates when a wall thimble is specified, it shall be of the same cast iron used in the gate frame and of the section, type, and depth specified. The front flange shall be machined to match the gate frame and drilled and tapped to accurately receive the gate attachment studs.

Gaskets or mastic to be installed between the thimble and the gate frame shall conform to the recommendations of the gate manufacturer and shall be furnished with the thimble.

9. GALVANIZING

Unless otherwise specified, cast steel and fabricated steel parts shall be galvanized in accordance with Material Specification [582](#).

10. PAINTING

When specified, gates and accessories shall be painted by the designated paint system.

11. INSTALLATION INSTRUCTIONS

The Contractor shall provide the Engineer with the manufacturer's complete installation data, instructions for adjustments, and drawings or templates showing the location of anchor bolts for each gate.

12. CERTIFICATION

The supporting data submitted to the Engineer shall include the name of the manufacturer, the manufacturer's model number (for standard catalogue items) or the seating head for which the gate is designed together with such drawings and specifications as may be necessary to show that the gate conforms to the requirements of this specification.

MATERIAL SPECIFICATION

573. RADIAL GATES

1. SCOPE

This specification covers the quality of radial (Tainter) gates for water control.

2. QUALITY OF MATERIALS

Materials in radial gates and appurtenances shall conform to the requirements of the applicable specifications listed below for the alloy, grade, type, or class of material and the condition and finish appropriate to the structural and operational requirements:

<u>Material</u>	<u>ASTM Specifications</u>
Cast iron	A 48, Class 30, or A 126, Class B
Cast steel	A 27 or A 148
Structural steel shapes, plates and bars	A 36
Carbon steel bars	A 108 or A 575
Stainless steel	A 167, A 276, or A 582 Type 302, 303, 304, or 304L
Zinc-coated steel sheets	A 653 or A 924
Bronze bar, rods, shapes	B 21 or B98
Cast Bronze	B 584

Galvanizing (zinc coating) shall conform to the requirements of Material Specification 582.

3. GATES

Unless otherwise specified, the gates shall be fabricated from structural steel with skin plates made of smooth or corrugated iron or steel sheets. They shall conform to the dimensions shown on the drawings and shall be built to withstand the specified head. The curvature of the skin plate shall be concentric with the pivot pins or trunnions. Gates shall be supplied with pin bearings, pins, hoist, galvanized hoisting cable and all anchor bolts. Unless otherwise specified, the pin bearings shall be cast iron and of the embedded type.

4. HOIST

Hoists shall be of the worm-gear type and shall be equipped with hand crank or be power operated as specified on the drawings. Hoists shall be furnished complete with all lubricants, anchor bolts and other appurtenances necessary for their installation and operation.

5. RUBBER SEALS

Each gate shall be fitted with rubber seals along the side and bottom edges of the gate face. The seals shall be of the belt type or "J" type, as specified, and shall be designed to bear on the walls and bottom of the structure or on rubbing plates and sills to insure a watertight fit when the gate is closed. When specified, a rubber seal shall also be provided at the top edge of the gate.

6. INSTALLATION INSTRUCTIONS

Prior to gate installation, the Contractor shall provide the Engineer with the manufacturer's complete installation data, instructions for adjustments and drawings or templates showing the location of anchor bolts and pin bearings for each gate.

7. PAINTING

Gates and accessories shall be galvanized or painted with the specified paint system.

8. CERTIFICATION

The supporting data submitted to the Engineer shall include the manufacturer's name and the hydraulic head for which the gate is designed together with such drawings and specifications as may be necessary to show that the gate conforms to the requirements of this specification.

MATERIAL SPECIFICATION

581. METAL

1. SCOPE

This specification covers the quality of steel and aluminum alloys.

2. STRUCTURAL STEEL

Structural steel shall conform to the requirements of ASTM A 36.

High-strength low-alloy structural steel shall conform to ASTM A 242 or A 588.

Carbon steel plates of structural quality to be bent, formed, or shaped cold shall conform the ASTM A 283, Grade C.

Carbon steel sheets of structural quality shall conform to ASTM Standard A 570, Grade D or A 611, Grade 40.

Carbon steel strip of structural quality shall conform to ASTM Standard A 570, Grade 36.

3. COMMERCIAL OR MERCHANT QUALITY STEEL

Commercial or merchant quality steel shall conform to the requirements of the applicable ASTM listed below:

<u>Product</u>	<u>ASTM Standards</u>
Carbon steel bars	A 575, Grade M 1015 to Grade M 1031
Carbon steel sheets	A 569
Carbon steel strips	A 569
Zinc-coated carbon steel sheets	A 653 or A 924

4. ALUMINUM ALLOY

Aluminum alloy products shall conform to the requirements of the applicable ASTM Standard listed below. Unless otherwise specified, alloy 6061-T6 shall be used.

<u>Product</u>	<u>ASTM Standards</u>
Standard Structural Shape	B 308
Extruded structural pipe and tube	B 429
Extruded bars, rods, shapes and tubes	B 221
Drawn seamless tubes	B 210
Rolled or cold-finished bars, rods and wire	B 211
Sheet and plate	B 209

5. BOLTS

Steel bolts shall conform to the requirements of ASTM Standard A 307. If high-strength bolts are specified, they shall conform to the requirements of ASTM A 325.

When galvanized or zinc-coated bolts are specified, the zinc coating shall conform to the requirements of ASTM Standard A 153; except that bolts 1/2 inch or less in diameter may be coated with electro-deposited zinc or cadmium coating conforming to the requirements of ASTM Standard B 633, Service Condition SC 3 or ASTM A 165, Type TS, unless otherwise specified.

6. RIVETS

Unless otherwise specified, steel rivets shall conform to the requirements of ASTM Specification A 502, Grade 1. Unless otherwise specified, aluminum alloy rivets shall be Alloy 606-T6 conforming to the requirements of ASTM Standard B 316.

7. WELDING ELECTRODES

Steel welding electrodes shall conform to the requirements of American Welding Society Specification AWS A5.1, "Specification for Mild Steel Covered Arc-Welding Electrodes," except that they shall be uniformly and heavily coated (not washed) and shall be of such a nature that the coating will not chip or peel while being used with the maximum amperage specified by the manufacturer.

Aluminum welding electrodes shall conform to the requirements of American Welding Society Specification AWS A5.10, "Specification for Aluminum and Aluminum-Alloy Welding Rods and Bare Electrodes."

MATERIAL SPECIFICATION

582. GALVANIZING

1. SCOPE

This specification covers the quality of zinc coatings applied to iron and steel productions.

2. QUALITY

Zinc coatings shall conform to the requirements of ASTM A 123 for Zinc (Hot-Dip Galvanized) Coatings on Iron and Steel Products or as otherwise specified in the items of work and construction details of the Construction Specification.

ASTM A 123 covers both fabricated and non-fabricated products e.g., assembled steel products, structural steel fabrications, large tubes already bent or welded before galvanizing, and wire work fabricated from non-coated steel wire. It also covers steel forgings and iron castings incorporated into pieces fabricated before galvanizing or which are too large to be centrifuged (or otherwise handled to remove excess galvanizing bath metal). Items to be centrifuged or otherwise handled to remove excess zinc shall meet the requirements of ASTM A 153, except: bolts, screws and other fasteners 1/2 - inch or less in diameter may be coated with electro-deposited zinc or cadmium coating conforming to the requirements of ASTM B 766, coating thickness Class 5, Type III or ASTM B 633, Service Condition SC-3 unless otherwise specified.

MATERIAL SPECIFICATION

583. COAL TAR-EPOXY PAINT

1. SCOPE

This specification covers the quality of a coal tar polyamide epoxy paint suitable for use on structural steel or concrete. Paint supplied meeting Paint Specification No. 16, Type 1, Class II, of the Steel Structures Painting Council will meet the requirements of this specification.

2. COMPOSITION AND PROCESSING

- a. Composition. The paint shall be a two-component system containing the pitch, filler and catalyst in one component and the resin in another. Each component of this paint based on the specified ingredients shall be uniform, stable in storage, and free from grit and coarse particles. The components shall contain the followings types and proportions of ingredients:

<u>Ingredient</u>	<u>COMPONENT A</u>		<u>COMPONENT A and B</u>
	<u>Percent by Weight Minimum</u>	<u>Maximum</u>	<u>Typical Composition Percent by Weight</u>
Coal Tar Pitch	33.0	36.0	28.2
Polyamide	11.0	12.0	9.5
Magnesium Silicate	30.0	33.0	25.8
Xylene	18.0	21.0	15.4
Gelling Agent and Activator	2.5	2.6	2.0
Catalyst (accelerator)	1.2	1.3	<u>1.1</u>
		Sub-Total	82.0
<u>COMPONENT B</u>			
Epoxy Resin (100% non-volatile)	100.0	----	<u>18.0</u>
		TOTAL	100.0

- b. Processing. Magnesium silicate and gelling agent shall be thoroughly dispersed in Component A by means of grinding equipment capable of developing substantial shear values. Gellant shall be mixed with an equal weight of magnesium silicate and then dampened by stirring-in all of the alcohol; the resultant mixture shall be added to and thoroughly dispersed into Component A. (The viscosity of Component A will be markedly influenced by the degree of dispersion of gellant and magnesium silicate.)

- c. Quality of Ingredients. Ingredient materials shall exhibit the following properties:

- (1) Coal Tar Pitch. Coal tar pitch is a product obtained from the distillation of high temperature crude coke oven tar, which in itself is a product obtained during the destructive distillation of coal in slot ovens operated at a

temperature above 700° C. Coal tar pitch shall have the following characteristics:

<u>Characteristic</u>	<u>Minimum</u>	<u>Maximum</u>
Softening point, in water, degree C (ASTM D 36)	70	75
Ash, percent by weight (ASTM D 2415)	--	0.5
Insolubles in carbon disulfide, percent by weight (ASTM D 4)	--	20
Volatiles, percent by weight Under 250° C	--	0.0
Under 300° C	--	5.0

- (2) Gellant The gellant or thixotropic-producing additive shall be an organic derivative of magnesium montorillonite or hydrogenated castor oil. It shall be a creamy white powder having a bulking value of 15 ± 0.2 pounds per gallon and water content of 3.0% maximum.
- (3) Activator The activator, if used, shall be methanol, ethanol, or propylene carbonate.
- (4) Catalyst The catalyst (accelerator) shall be 2, 4, 6 - tri (dimethylamino methyl) phenol.
- (5) Epoxy Resin Epoxy resin shall be a di-epoxide condensation product of bisphenol-A and epichlorohydrin with terminal epoxide group. It shall be clear, free of turbidity, crystals, and particulate matter with the following properties:

<u>Property</u>	<u>Requirements</u>	
	<u>Minimum</u>	<u>Maximum</u>
Non-volatile content (1-2 grams after 1 hour @ 105 ± 2°C), % by weight	99	--
Epoxide equivalent (ASTM D 1652)	180	200
Color, Gardner (ASTM D 1544)	--	5.0
Specific Gravity (ASTM D 1475)	1.15	1.18
Viscosity, Brookfield, Poises @ 25° C	100	160

- (6) Polyamide Resin. Polyamide resin shall be a condensation product of a dimerized fatty acid in polyamides. It shall be clear, free of turbidity and particulate matter with the following characteristics:

<u>Characteristic</u>	<u>Requirements</u>	
	<u>Minimum</u>	<u>Maximum</u>
Amine Value <u>1/</u>	330	360
Color, Gardner (ASTM D 1544)	--	9
Specific Gravity (ASTM D 1475)	0.96	0.98
Viscosity, Brookfield, Poises @ 25° C	7	9
Non-volatile Content, (1-2 grams after 1 hour/105 ± 2° C), percent by weight	97	--

1/ The amine value is defined as the milligrams of potassium hydroxide equivalent to the amine alkalinity potentiometric titration with standard perchloric acid according to the following method:

- A. Weigh the approximate amount of well mixed resin to give a titration in the range of 12 to 18 milliliters(ml) into a tared 200 ml berzelius tall form beaker on an analytical balance. Cover the beaker with aluminum foil to minimize contact with air.
- B. From a graduated cylinder, carefully add 90 ml of solvent (suitable solvents are nitrobenzene, propylene carbonate, or acetonitrile), insert a stirring bar, cover the beaker with aluminum foil, and stir on a magnetic stirrer to dissolve the sample. Add the solvent immediately after weighing the sample. A fume hood should be used for all operations.
- C. From a graduated cylinder, add 20 ml of glacial acetic acid to the sample solution and stir for several minutes.
- D. Immerse the electrodes into the sample solution, stir for two (2) minutes and titrate potentiometrically with 0.1 N perchloric acid using the millivolt scale. Record the millivolt reading every 0.1 ml. Plot a graph showing the millivolts against the titration. The endpoint is the midpoint of the inflection on the titration curve.
- E. Conduct a blank determination on 90 ml of the solvent and 20 ml of acetic acid. The blank need only be determined once for each lot of solvent used. on the majority of lots used, the blank has been found to be zero.
- F. Calculate the amine value using the following formula:

$$\text{AMINE VALUE} = \frac{(\text{sample Titration} - \text{Solvent Blank}) \times \text{Normality} \times 56.1}{\text{Weight of Sample}}$$

(7) Xylene Xylene shall conform to ASTM D 846.

(8) Magnesium Silicate Magnesium silicate shall conform to ASTM Standard D 605 "Magnesium Silicate Pigment (Talc)". When a dark red colored coating is specified, a dark red coating shall be furnished in 50% or more (by volume) of the magnesium silicate is replaced by synthetic red iron conforming to ASTM Standard D 3721. The red coating shall meet all of the test requirements prescribed for the black coating, except that the non-volatile content of Component A shall be an amount reflecting the greater specific gravity of the iron oxide pigment.

3. PHYSICAL REQUIREMENTS

When tested by the methods described in Section 4:

a. Component A shall exhibit the following properties:

- (1) Viscosity, Brookfield, @ 25° C poises 160 maximum
- (2) Non-volatile residue, percent by weight 77 minimum

b. The mixed paint shall exhibit the following properties:

- | | |
|---------------------------------|-----------|
| (1) Sag, 14 mil wet film | None |
| (2) Pot life at 24-27° C, hours | 4 Minimum |
- c. The cured film shall exhibit the following properties:
- | | |
|--|-----------------|
| (1) Penetration, 200 grams, 5 seconds, 25° C, hundredth centimeter units | 3 Maximum, |
| (2) Odor after 48 hours curing | Pass test |
| (3) Flexibility on 1/2 inch mandrel | Pass test |
| (4) Adhesion | No delamination |

4. TEST METHODS

a. Viscosity of Component A Fill a container having a minimum diameter of 3-inches, a minimum height of 3 3/4 inches, and a minimum depth of 3 inches with a representative sample of Component A. Set up a Model RVT or RVF-100 Brookfield Synochro-Electric Viscometer with a No. 7 spindle and with guard removed. Bring the sample to (and thereafter maintain) a temperature of 25° C and stir vigorously for two (2) minutes with a stiff spatula. Immediately after stirring, lower the viscometer, immersing the spindle until one-half (1/2) of the "neck" mark on the spindle is covered. Run the viscometer at 100 rpm for one (1) minute and record the pointer position on the dial. If the dial reading is 40 or less, the viscosity shall be considered to be 160 Poises or less. If the reading is

over 40, immediately start the motor and take additional readings at one (1) minute intervals. If one or more readings of 40 or less are obtained out of 10 readings, taken at 1-minute intervals, the viscosity of the material shall be considered to be with specification limits

- b. Non-volatile Content of Component A Place a stirrer (e.g., short length of stiff wire such as a partially-straightened paper clip) into a small disposable aluminum dish of about two (2) inches in diameter and weigh to the nearest 0.1 milligram. As rapidly as possible, place between 2 and 3 grams of Component A into the dish and weigh immediately to the nearest 0.1 milligram. After weighing, spread the material over the bottom of the dish. Heat the dish, wire, and contents in a well ventilated convection-type oven maintained at $105^{\circ}\text{C} \pm 2^{\circ}\text{C}$, for three (3) hours. After the material has been in the oven for a few minutes, and periodically thereafter, stir the material. Cool in a desiccator, weigh to the nearest 0.1 milligram, and calculate the percentage of non-volatile on a weight basis.
- c. Sag Test of Coal Tar-Epoxy Paint Prepare approximately 500 milliliters of the material by thoroughly mixing 100 ml of Component B into 400 ml of Component A. Determine its viscosity immediately after mixing, using the same procedure as for Component A above but employing a No. 5 spindle. If all of five (5) readings recorded at 1-minute intervals are above 50, reduce the viscosity by adding xylene in small increments until a reading not greater than 50 is obtained. Press a strip of 1-inch masking tape across the full width of a solvent-cleaned 3-inch by 6-inch cold-rolled steel panel. The tape should be parallel to and centered on the shorter axis of the panel. Within five (5) minutes after making the final check of viscosity, apply the material to the panel to a wet film thickness at least 14 mils as determined by an Interchemical wet film doctor blade having a gap of approximately 25 mils or by brush. Immediately after applying the material, carefully remove the masking tape and stand the panel in a vertical position (with the bare strip horizontal) in a draft-free, $24\text{-}27^{\circ}\text{C}$ location. Examine the panel after 4 hours. Sagging or running of the coating into the bare area shall constitute failure of the material to pass the sag test.
- d. Pot Life Test of Coal Tar-Epoxy Paint Mix 100 ml of Compound B into 400 ml of Component A with both components having a temperature of $24\text{-}27^{\circ}\text{C}$ before mixing. Pour the material at once into a pint metal can, seal tightly, and maintain at $24\text{-}27^{\circ}\text{C}$. Examine the material 4 hours after it was mixed.

For its pot life to be considered satisfactory, the mixed material must have remained in a fluid condition and, when thinned with no more than 100 ml of xylene, shall be lump-free and brushable.

- e. Penetration Test on Coal Tar-Epoxy Film Select and solvent spray-clean two 3-inch by 6-inch cold-rolled steel panels in accordance with ASTM D 609. Draw down in accordance with a coat of the paint prepared as described in 4.c. for the sag test. Allow the film to dry 18 to 24 hours in a horizontal position at $24\text{-}27^{\circ}\text{C}$ and at a relative humidity of not over 60%. Apply a second coat over and at right

angles to the first coat, using freshly mixed paint prepared identically to that used for the first coat. The draw down applicator(s) shall be such as to provide a total dry-film thickness for the two coats of 20-25 mils, and the coats shall be of approximately equal thickness. Allow the second coat to dry in a horizontal position for 120 hours at 24-27° C. After 120 hours of curing, and daily thereafter, clamp the panel into the table of a penetrometer (ASTM D 5) so that the needle is over an area which is within the prescribed thickness range (as measured by ASTM D 1186) and determine the penetration, using a total load of 200 grams applied for 5 seconds at 25° C. The average of the three lowest out of five penetration readings, all taken within a 1 centimeter square, shall not exceed 0.03 of a centimeter after 120 hours of curing.

- f. Odor of Dried Coal Tar-Epoxy Film Examine the paint film on one of the flexibility panels for odor after it has cured for 48-hours. The film shall be free of any odor except for a faint odor of xylene.
- g. Flexibility of Coal Tar-Epoxy Film Sand blast three (3) steel panels (similar to those used in the penetration test) at low pressure with a clean, 30 to 50 mesh, non-metallic abrasive until a uniform, gray-white surface, with well developed anchor pattern, is achieved. (Note: It may be necessary to blast both sides of panel, in stages, to avoid warping.) Blow off any dust with a clean air blast. Apply two (2) coats of paint as described in 4.e. for the penetration test. Allow the film to cure in the period equal to that required to reach a penetration of 0.03 centimeter on the penetration test panel, whichever occurs first. With the film side up, and in a time interval of approximately one (1) second, bend each of the flexibility panels double over a 1/2 inch diameter mandrel. Cracks in any of the panels visible to the naked eye shall constitute failure except that edge cracks extending no further than 1/2-inch or small local fissures emanating from air bubbles, craters, and similar imperfections shall be disregarded.
- h. Adhesion of Coal Tar-Epoxy Film Test the adhesion of the coating on an unbroken area of the flexibility panel with a sharp knife after the coating has cured for 120 hours. It shall strongly resist being removed from the metal. Also, test the intercoat adhesion of the film on a penetration panel after 120 hours curing, with a knife. Any delamination of the two (2) coats shall constitute failure.

MATERIAL SPECIFICATION

584. STRUCTURAL TIMBER AND LUMBER

1. SCOPE

The specification covers the quality of structural timber, lumber and plywood.

2. GRADING

Structural timber and lumber shall be graded in accordance with the grading rules and standards, applicable to the specified species, adopted by a lumber grading or inspection bureau or agency recognized as being competent and that conform to the basic principles of ASTM Standard D 245. The material supplied according to the commercial grading rules shall be of equal or greater stress value than the specified stress-grade.

3. QUALITY

All materials shall be sound wood free from decay and disease damage. Boxed heart pieces of Douglas fir or redwood shall not be used in stringers, floor beams, caps, posts, sills or other principal structural members. Boxed heart pieces are defined as timber so sawed that at any section in the length of a sawed piece the pith lies entirely inside the four faces.

4. HEARTWOOD REQUIREMENTS

All timber and lumber specified for use without preservative treatment shall contain a minimum of 75 percent heartwood on any diameter or on any side or edge, measured at the point where the greatest amount of sapwood occurs. This requirement shall not apply to timber and lumber for which pressure treatment with wood preservative is specified.

5. SIZES

The sizes specified are nominal sizes. Unless otherwise specified, the material shall be furnished in American Standard dressed sizes.

6. MARKING

Each piece of timber and lumber shall be legibly stamped or branded with an official grade identification. Plywood shall be legibly stamped with an official mark designating the grade, type and surface finish as described in the cited Product Standard.

MATERIAL SPECIFICATION

585. WOOD PRESERVATIVES AND TREATMENT

1. SCOPE

This specification covers the quality of wood preservatives and methods of treatment of wood products.

2. TREATING PRACTICES

Treating practices and sampling, inspection and test procedures shall conform to the requirements of ASTM D 1760, "Standard Specification for Pressure Treatment of Timber Products".

3. PRESERVATIVES

The wood shall be treated with the specified type of preservative. Wood preservatives shall conform to the requirements of the applicable specifications list in ASTM D 1760.

4. QUALITY OF TREATED MATERIALS

Treated lumber, timber, piles, poles, or posts shall be free from heat checks, water bursts, excessive checking, results of chafing or from any other damage or defects that would impair their usefulness or durability for the purpose intended. The use of "s" irons will not be permitted. Holes bored for tests shall be filled with tight fitting treated wood plugs.

5. MARKING

Each treated wood item delivered to the job site shall be marked as specified in ASTM D 1760, unless otherwise specified.

MATERIAL SPECIFICATION

591. FIELD FENCING MATERIALS

1. SCOPE

This specification provides the minimum quality requirements for the material used in the construction of field fences.

2. WIRE GAUGE

When the size of steel wire is designated by gage number, the diameter shall be as defined for U. S. Steel Wire Gage.

3. FENCING

Fencing materials shall conform to the requirements of ASTM A 121 for barbed wire, ASTM A 116 for woven wire, ASTM A 390 for poultry fence or netting, and ASTM A 854 for high-tensile wire. Barbed wire and woven wire shall be Class 3 zinc coated, unless otherwise specified. High-tensile wire shall have Type I zinc coating, unless otherwise specified.

4. STAYS, FASTENERS, AND TENSION WIRE

Stays and fasteners shall conform to the requirements of the appropriate ASTM for the fencing material specified, unless otherwise specified. Tension wires shall have a tensile strength not less than 58,000 pounds per square inch. Stays, fasteners and tension wire shall have Class 3 zinc coating as specified in ASTM A 641.

5. WOOD FENCE POSTS AND BRACES

Unless otherwise specified, wood posts shall be of black locust, red cedar, osage orange (Bois d'Arc), redwood, pressure treated pine or other wood of equal life and strength. At least half the diameter or diagonal dimension of red cedar or redwood posts shall be in heartwood. Pressure treatment shall conform to Material Specification [585, Wood Preservatives and Treatment](#). The posts shall be sound, new, and free from decay, with all limbs trimmed substantially flush with the body. All posts shall be substantially straight throughout their full length.

Wood braces shall be of wood material equal to or better than construction grade Douglas Fir. Wood braces shall be pressure treated in conformance with Material Specification 585.

6. STEEL FENCE POSTS AND BRACES

Steel fence posts and braces shall conform to the requirements of ASTM A 702 for steel fence posts and ASTM A 53 for bracing pipes. Posts with punched tabs for fastening the wires shall not be installed.

7. CONCRETE FENCE POSTS

Concrete fence posts shall be manufactured to the specified requirements of size, shape, and strength.

8. PANEL GATES

Panel gates shall be the specified types, sizes, and quality and shall include the necessary fittings required for installation. The fittings shall consist of not less than two hinges and one latch or galvanized chain for fastening. Latches shall be of such design that a padlock may be used for locking. All fittings shall not be of lesser quality than the gate manufacturer's standard.

9. WIRE GATES

Wire gates shall be the type shown on the drawings, constructed in accordance with specifications, at the locations, and to the dimensions shown on the drawings. The materials shall conform to the kinds, grades, and sizes specified for new fence, and shall include the necessary fittings and stays.

10. STAPLES

Staples required to secure the fence wire to wood posts shall be 9-gauge galvanized wire with a minimum length of 1-1/2 inches for soft woods and a minimum length of one (1) inch for close-grain hardwoods.

11. GALVANIZING

All iron and steel fencing materials, except as otherwise specified, shall be zinc coated by the hot dip process meeting the requirements of Material Specification [582](#), except that clips, bolts, and other small hardware may be protected by electro-deposited zinc or cadmium coating.

MATERIAL SPECIFICATION

592. GEOTEXTILE

1. SCOPE

This specification covers the quality of geotextiles.

2. GENERAL REQUIREMENTS

Fibers (threads and yarns) used in the manufacture of geotextile shall consist of synthetic polymers composed of a minimum of 85 percent by weight polypropylenes, polyesters, polyamides, polyethylene, polyolefins, or polyvinylidene-chlorides. They shall be formed into a stable network of filaments or yarns retaining dimensional stability relative to each other. The geotextile shall be free of defects and conform to the physical requirements contained in Tables 1 and 2. The geotextile shall be free of any chemical treatment or coating that significantly reduces its porosity. Fibers shall contain stabilizers and/or inhibitors to enhance resistance to ultraviolet light.

Thread used for factory or field sewing shall be of contrasting color to the fabric and made of high strength polypropylene, polyester, or polyamide thread. Thread shall be as resistant to ultraviolet light as the geotextile being sewn.

3. CLASSIFICATION

Geotextiles shall be classified based on the method used to place the threads or yarns forming the fabric. The geotextiles will be grouped into the types described below:

- a. Woven. Fabrics formed by the uniform and regular interweaving of the threads or yarns in two directions.

Woven fabrics shall be manufactured from monofilament yarn formed into a uniform pattern with distinct and measurable openings, retaining their position relative to each other. The edges of fabric shall be selvaged or otherwise finished to prevent the outer yarn from unraveling.

- b. Non-woven. Fabrics formed by a random placement of threads in a mat and bonded by heat-bonding, resin-bonding, or needle punching.

Non-woven fabrics shall be manufactured from individual fibers formed into a random pattern with distinct but variable small openings, retaining their position relative to each other when bonded by needle punching, heat, or resin bonding. The use of non-wovens, other than the needle-punched geotextiles, is somewhat restricted (see Note 3 of Table 2).

4. SAMPLING AND TESTING

The geotextile shall meet the specified requirements (Table 1 or 2) for the product style shown on the label. Product properties as listed in the latest edition of the "Specifiers Guide", Geotechnical Fabrics Report, ADDRESS: Industrial Fabrics

Association International, 1801 County Road BW, Roseville, MN 55113-4061; and that represents minimum average roll values, will be acceptable documentation that the product style meets the requirements of these specifications.

For products that do not appear in the above directory, or do not have minimum average roll values listed, typical test data from the identified production run of the geotextile will be required for each of the specified tests (Table 1 or 2) as covered under clause AGAR 452.236-76.

5. SHIPPING AND STORAGE

The geotextile shall be shipped/transported in rolls wrapped with a cover for protection from moisture, dust, dirt, debris, and ultraviolet light. The cover shall be maintained undisturbed to the maximum extent possible prior to placement.

Each roll of geotextile shall be labeled or tagged to clearly identify the brand, Class and the individual production run in accordance with ASTM D 4873.

TABLE 1
REQUIREMENTS FOR WOVEN GEOTEXTILES

Property	Test Method	Class I	Class II & III	Class IV
Tensile Strength (pounds) <u>1/</u>	ASTM D 4632 Grab Test	200 minimum in any principal direction	120 minimum in any principal direction	180 minimum in any principal direction
Bursting Strength (psi) <u>1/</u>	ASTM D 3786 Diaphragm Tester	400 minimum	300 minimum	NA
Elongation at Failure (percent) <u>1/</u>	ASTM D 4632 Grab Test	<50	<50	<50
Puncture (pounds) <u>1/</u>	ASTM D 4833	90 minimum	60 minimum	60 minimum
Ultraviolet Light (percent residual tensile strength)	ASTM D 4355 150-hours exposure	70 minimum	70 minimum	70 minimum
Apparent Opening Size (AOS)	ASTM D 4751	As specified or a minimum # 100 <u>2/</u>	As specified or a minimum # 100 <u>2/</u>	As specified or a minimum # 100 <u>2/</u>
Percent Open Area (percent)	CWO-02215-86	4.0 minimum	4.0 minimum	1.0 minimum
Permittivity sec ⁻¹	ASTM D 4491	0.10 minimum	0.10 minimum	0.10 minimum

1/ Minimum average roll value (weakest principal direction).

2/ U.S. Standard Sieve Size.

NOTE: CWO is a USACE reference.

TABLE 2
REQUIREMENTS FOR NON-WOVEN GEOTEXTILES

Property	Test Method	Class I	Class II	Class III	Class IV <u>3/</u>
Tensile Strength (pounds) <u>1/</u>	ASTM D 4632 Grab Test	180 minimum	120 minimum	90 minimum	115 minimum
Bursting Strength (psi) <u>1/</u>	ASTM D 3786 Diaphragm Tester	320 minimum	210 minimum	180 minimum	NA
Elongation at Failure (percent) <u>1/</u>	ASTM D 4632	≥50	≥50	≥50	≥50
Puncture (pounds) <u>1/</u>	ASTM D 4833	80 minimum	60 minimum	40 minimum	40 minimum
Ultraviolet Light (percent residual tensile strength)	ASTM D 4355 150-hours exposure	70 minimum	70 minimum	70 minimum	70 minimum
Apparent Opening Size (AOS)	ASTM D 4751	As specified or a maximum #40 <u>2/</u>	As specified or a maximum # 40 <u>2/</u>	As specified or a maximum # 40 <u>2/</u>	As specified or a maximum # 40 <u>2/</u>
Permittivity sec ⁻¹	ASTM D 4491	0.70 minimum	0.70 minimum	0.70 minimum	0.10 minimum

1/ Minimum average roll value (weakest principal direction).

2/ U.S. Standard Sieve Size.

3/ Heat-bonded or resin-bonded geotextile may be used for Class III and IV. They are particularly well suited for Class IV. Needle-punched geotextiles are required for all other classes.

MATERIAL SPECIFICATION

593. LIME

1. SCOPE

This material specification covers the quality of hydrated lime used in the treatment of clayey soils.

2. QUALITY

a. Hydrated Lime

- (1) Hydrated lime shall meet the following requirements when tested in accordance with ASTM C 25 or ASSHTO T 219.

Minimum available lime, reported as $\text{Ca}(\text{OH})_2$ = 90 percent.

Maximum carbon dioxide (as-received basis) = seven (7) percent.

- (2) The physical gradation of hydrated lime when tested in accordance with ASTM C 110 shall meet the requirements of ASTM C 977.

MATERIAL SPECIFICATION

594. HDPE AND LLDPE FLEXIBLE MEMBRANE LINER

1. SCOPE

This specification covers the quality of High Density Polyethylene (HDPE) and Low Linear Density Polyethylene (LLDPE) flexible liner, seams, gaskets, metal battens, embed channels, clamps, and sealant.

2. MATERIAL

Liner. The HDPE or LLDPE liner shall have a nominal thickness of 30 mils, 40 mils, or 60 mils as specified. The liner shall be manufactured to be suitable for use in either exposed or buried conditions. It shall conform to the requirements of this specification as shown in tables 594–1 through 594–4. It shall also meet the requirements of Construction Specification 97 and the requirements shown on the drawings.

Gaskets, metal battens, clamps, embed channels, and sealant. Gasket material shall be neoprene, closed cell medium, 0.25 inch thick, with adhesive on one side, or other gasket material as approved by the liner manufacturer. Metal battens shall be 0.25 inch thick by 2 inches wide stainless steel. Clamps shall be 0.5-inch-wide stainless steel. Embed channel shall have the same properties as the liner. Sealant shall be General Electric Silicone, RTV 103, or equivalent.

3. HDPE AND LLDPE LINER PROPERTIES

The HDPE or LLDPE liner shall be manufactured from virgin polymer material and shall meet the property values specified under tables 594–1 through 594–4 as applicable.

Table 594-1 Requirements for smooth HPDE liner

Property	Test methods	Requirements*		
		----- nominal thickness -----

** Film tear bond: A failure of one of the bonded sheets by tearing prior to complete separation in the bonded area.

MATERIAL SPECIFICATION

595. GEOSYNTHETIC CLAY LINER

1. SCOPE

This specification covers the quality of geosynthetic clay liner (GCL) material and workmanship.

2. GENERAL REQUIREMENTS

The GCL is composed of a layer of high shrink-swell sodium bentonite sandwiched between a layer of 6 ounces per square yard nonwoven polypropylene geotextile and a layer of 3.2 ounces per square yard woven geotextile. The GCL material shall be manufactured by one of the following processes:

- a. Needle punched process by which the bentonite is encapsulated between the geotextile layers by a mechanical bonding process without the use of any chemical binders or adhesive, or
- b. Lock stitched to provide internal shear strength and the integrity and consistency to the thickness and unit weight of the material.

The bentonite shall have the following base properties:

- a. A minimum of 0.75 pound per square foot of high shrink/swell sodium bentonite at 12 percent moisture. If the liner material is manufactured at higher moisture content, it shall still meet the above requirements when adjusted to the 12 percent moisture level.
- b. Swell index—minimum 24 ml per 2 grams.
- c. Fluid loss—maximum 18 ml

The GCL shall have an index flux value no larger than 1×10^{-8} m/s

3. PACKAGING AND LABELING

All material shall be packaged in individual rolls of a minimum of 3.65 meters wide and with at least 30.5 meters in length on the roll. All rolls shall be labeled and in a wrapping that is resistant to UV light deterioration. The labels on each roll shall identify the length and width of the roll, the manufacturer, the product, lot number, and the roll number.

4. TESTING AND QUALITY CONTROL

The following tests shall be performed and the results certified by the manufacturer:

Swell index	ASTM D 5890
Fluid loss	ASTM D 5891
Bentonite mass/unit area	ASTM D 5993
Index flux	ASTM D 5887
Mass/unit area, geotextile	ASTM D 3776

5. INSPECTION AND MAINTENANCE

No liner material shall be accepted for placement in the permanent works that has not been certified by the manufacturer as meeting all specified requirements. No liner material shall be accepted that exhibits any visible defects. The liner material shall be subject to quality assurance testing at any time before and during installation.

MATERIAL SPECIFICATION

800. PAPER AND PLASTIC NETTING

1. SCOPE

This specification covers the quality of paper netting, plastic netting, and staples.

2. PAPER NETTING

Paper netting shall be made of tight twisted, paper yarn, plain woven and shall be furnished in rolls and meet the following minimum requirements:

- a. Width - minimum 45 inches, + or -1 inch from manufacturer's rated width.
- b. Spacing between strands shall be approximately 1/2 to 1 inch by 2 inches.
- c. Selvage edges shall be reinforced with polypropylene filament.
- d. Weight shall average 8.8 pounds per 100 square yards with a tolerance of + or - 5%.
- e. All material shall be new and unused, and the length and weight shall be marked on each roll.

3. PLASTIC NETTING

Plastic netting shall be made of extruded polypropylene (plastic) and shall be furnished in rolls and shall meet the following minimum requirements:

- a. Width - Minimum 48 inches, + or - 1 inch from manufacturer's rated width.
- b. Spacing between strands shall be approximately 1 x 2 inches.
- c. Weight shall average 2.4 pounds per 100 square yards with a tolerance of + or - 5%.
- d. All material shall be new and unused and the length and weight shall be marked on each roll.

4. STAPLES

"U" shaped wire staples of 0.12 inch in diameter (No. 11 wire gage) or greater, with a minimum leg length of 6 inches and a minimum crown of 1 inch shall be used. In sandy soils the minimum leg length of staples shall be 9 inches.

MATERIAL SPECIFICATION

801. JUTE NETTING

1. SCOPE

This specification covers the quality of jute netting and staples.

2. JUTE NETTING

Jute netting shall be of a uniform, open, plain weave, undyed and unbleached single jute yarn. The yard shall be of loosely twisted construction and shall not vary in thickness by more than one-half its normal diameter. Jute netting shall be furnished in rolls and shall meet the following minimum requirements:

- a. Width - Minimum 48 inches, + or - 1 inch from manufacturer's rated width.
- b. Seventy-eight warp ends per 4 feet of width.
- c. Forty-one weft ends per yard.
- d. Weight shall average 1.22 pounds per linear yard (based on 48 inch width) with a tolerance of + or - 5%.
- e. All material shall be new and unused, and the length shall be marked on each roll.

3. STAPLES

"U" shaped wire staples of 0.12 inch in diameter (No. 11 wire gage) or greater, with a minimum leg length of 6 inches and minimum crown of 1 inch shall be used. In sandy soils the minimum leg length of staples shall be 9 inches.

MATERIAL SPECIFICATION

802. EXCELSIOR BLANKETS

1. SCOPE

This specification covers the quality of excelsior blankets and staples.

2. EXCELSIOR EROSION CONTROL BLANKETS

The blanket shall consist of a machine produced mat of curled wood excelsior and shall be furnished in rolls and meet the following minimum requirements:

- a. Width - 48 inches, + or - 1 inch.
- b. Length - approximately 180 feet.
- c. Weight - 0.8 lbs. per square yard, + or - 10%.
- d. Fiber length - 80% shall be 6 inches or longer.
- e. Fiber dimension - 0.021 inch x 0.042 inch, + or - 25%.
- f. The top of each blanket shall be covered with 1 x 2 inch extruded plastic mesh.
- g. Blankets shall be smolder resistant and shall meet the test of no-flame or smolder for more than a distance of 12 inches from a spot where a lighted cigarette is placed on the blanket's surface.
- h. All material shall be new and unused and the length shall be marked on each roll.

3. STAPLES

"U" shaped wire staples of 0.12 inch in diameter (No. 11 wire gage) or greater, with a minimum leg length of 6 inches and minimum crown of 1 inch shall be used. In sandy soils the minimum leg length of staples shall be 9 inches.

MATERIAL SPECIFICATION

803. STRAW BLANKETS

1. SCOPE

This specification covers the quality of straw blankets and staples.

2. STRAW EROSION CONTROL BLANKET

The blanket shall consist of a machine produced mat of straw or combination of straw and coconut fiber and shall be furnished in rolls and meet the following minimum requirements:

- a. Width - 66 inches, + or - 1 inch.
- b. Length - 83.5 feet.
- c. Weight - 0.75 lbs. per sq. yd., + or - 10%.
- d. Material - not less than 70 percent straw.
- e. The blanket shall be bound with a biodegradable cotton thread.
- f. The top of each blanket shall be covered with a photodegradable netting.
- g. All material shall be new and unused and the length shall be marked on each roll.

3. STAPLES

"U" shaped wire staples of 0.12 inch in diameter (No. 11 wire gage) or greater, with minimum leg length of 6 inches and minimum crown of 1 inch shall be used. In sandy soils the minimum leg length of staples shall be 9 inches.

MATERIAL SPECIFICATION

804. MATERIAL FOR TOPSOILING

1. SCOPE

This specification covers the quality of material for use in topsoiling.

The site shall be explored to determine if sufficient surface soil of good quality exists to justify stripping. Stripping of topsoil from areas where it will later be reapplied is not recommended if bedrock or other root limiting layer is within a depth of 20 inches.

2. QUALITY

Topsoil shall be friable and loamy (loam, sandy loam, silt loam, sandy clay loam, or clay loam). Sand content shall generally be less than 70% by weight, and clay content shall generally be less than 35% by weight.

Organic soils, such as peat or muck, shall not be used as topsoil material.

Organic matter content shall be not less than 1.5% by weight.

pH shall be within the range 6.0 to 7.5. If pH is less than 6.0, lime shall be added in accordance with soil test results or in accordance with the recommendations of the vegetative establishment practice being used.

Soluble salts shall not exceed 500 ppm. (Natural soils in Illinois rarely exceed this parameter.)

Sodium adsorption ratio shall be less than 12. (Natural soils in the northern one-half of Illinois rarely exceed this parameter.)

It shall be free of debris, trash, stumps, rocks, and noxious weeds, and shall give evidence of being able to support healthy vegetation. It shall contain no substance that is potentially toxic to plant growth.

The material meeting the above qualifications should be at least 2 inches thick. Soil factors such as rock fragments, slope, depth to water table, and layer thickness affect the ease of excavation and spreading of topsoil.

Generally, the upper part of the soil profile, which is richest in organic matter, is most desirable; however, material excavated from deeper layers may be worth storing if it meets the other criteria listed above.

SECTION 7 - STANDARD DRAWINGS

INTRODUCTION

This section contains standard drawings to be used with the construction and material specifications. Together with the specifications many jobs can be designed and constructed without a large engineering input. Standard drawings are intended for small jobs and usually have limits to avoid situations that require more detailed engineering design.

Many of the standard drawings require additional information before use. Practice dimensions often vary with site features. The dimensions and labels to make the drawings match the requirements imposed by site conditions should be included on the provided blanks in the drawings where appropriate.

The standard drawings dated before January 1999 were created using VersaCad Version 6.0 Software. New and revised drawings since January 1999 were created using AutoCad version 14, AutoCad LT 97, and AutoCAD 2000 software. All of the standard drawings created in versions prior to AutoCAD 2000 have been converted to AutoCAD 2000 (.dwg) format. This conversion from VersaCad to AutoCAD 2000 format resulted in some loss of information. Every effort has been made to rectify these discrepancies, but some caution is recommended to ensure that the drawings contain the required information before use.

All references to IDOT in the standard drawings refer to the *Illinois Department of Transportation Standard Specifications for Road and Bridge Construction*, Adopted January 1, 2002. The standard drawings use an 'RR' designation in place of a gradation number. Assume the 'RR' to be synonymous with 'Gradation'.

All of the drawings are available in the DXF format. This will allow conversion of the drawings into most CAD systems. For non-AutoCAD users, the drawings are also available in DWF and PDF format. DWF files can be viewed and printed by downloading Autodesk WHIP! software. PDF files can be viewed and printed by downloading Adobe Acrobat software. Using WHIP! software with the DWF files is the preferred method for obtaining electronic versions of the standard drawings for non-AutoCAD users because it preserves many of the AutoCAD features, such as layer control and cursor location.

This section was revised in December 2002.

DRY FIRE HYDRANT - DETAILS

NOTE: If Pump Is Higher Than Steamer Nozzle, Measure H From Pump Level.

PROFILE OF INSTALLATION

CALCULATING REQUIRED LIFT

TOTAL REQUIRED LIFT =
 HEAD LOSS IN HYDRANT, + HEAD LOSS IN INTAKE + STATIC LIFT (H)
 FITTINGS AND GUARD PIPE (HL)

USING 500 GALLONS/MIN.

$$\text{TOTAL REQUIRED LIFT} = 7.6' + \frac{L \times \text{HL}}{100} + H = 7.6' + \underline{\quad} + \underline{\quad} = \underline{\quad}$$

USING 250 GALLONS/MIN.

$$\text{TOTAL REQUIRED LIFT} = 1.9' + \frac{L \times \text{HL}}{100} + H = 1.9' + \underline{\quad} + \underline{\quad} = \underline{\quad}$$

ILLINOIS	
Altitude (Feet)	Allowable Lift (Feet)
300	22.7
1,000	22.0
1,300	21.8

HEAD LOSS IN FEET (HL)		
Gallons Per Minute	Plastic Pipe	Smooth Steel Pipe
500	2.3	5.3
250	0.6	1.3

NOTE: Total required lift value not to exceed value obtained from table of allowable lifts (above).

CONSTRUCTION ROAD STABILIZATION

PLAN VIEW

SECTION A-A

NOTES:

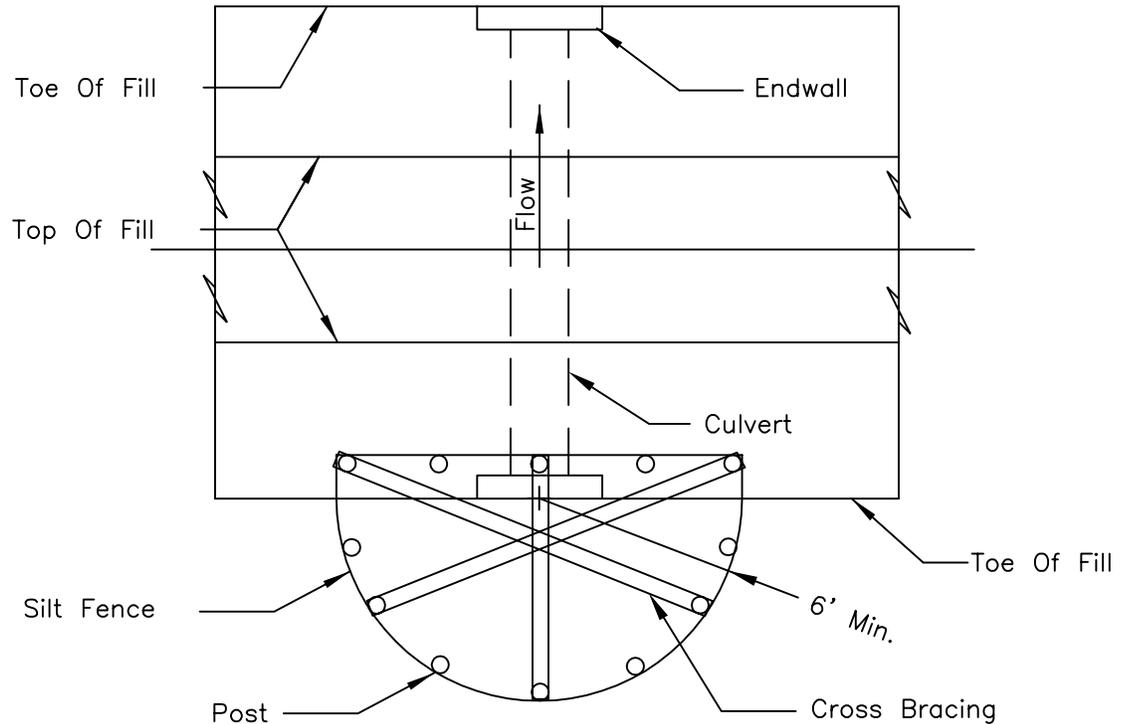

1. Filter fabric shall meet the requirements of material specification 592 GEOTEXTILE, Table 1 or 2, Class I, II or IV and shall be placed over the cleared area prior to the placing of rock.
2. Stone shall meet one of the following IDOT coarse aggregate gradations, CA-1, CA-2, CA-3, or CA-4 and be placed according to construction specification 25 ROCKFILL using placement Method 1 and Class III compaction.
3. See plans for construction road location, D and W dimensions.
4. Minimum width is 14 feet for one-way traffic and 20 feet for two-way traffic. Two-way traffic widths shall be increased a minimum of 4 feet for trailer traffic. Depending on the type of vehicle or equipment, speed, loads, climatic and other conditions under which vehicles and equipment operate an increase in the minimum widths may be required.
5. Roadway shall follow the contour of the natural terrain to the extent possible.

Notes:

1. Sediment shall be removed when the sediment has accumulated to one-half the height of the stone berm.
2. Coarse aggregate shall meet one of the following IDOT coarse aggregate gradations, CA-1, CA-2, CA-3 or CA-4.
3. Riprap shall meet IDOT gradation RR-3 or RR-4. Any permanent riprap, such as for the culvert headwall, shall meet IDOT Quality Designation A.
4. Coarse aggregate and riprap shall be placed according to construction specification 25 ROCKFILL using placement Method 1 and Class III compaction.
5. The maximum drainage area to the culvert being protected is 3 acres.
6. See plans for H dimension.
7. Tie the stone berm into the culvert embankment a minimum of 1 foot above the design elevation of the stone berm.

INLET FOR UNDERGROUND OUTLET - PLASTIC

NOTES:

1. Plastic Pipe: Polyvinyl Chloride (PVC) or High Density Polyethylene (PE) pipe with SDR equal to 43 or less.
2. The above ground portion of the inlet, must have holes evenly spaced around the circumference of the pipe, as shown below:

Inlet Diameter (Inches)	Minimum Number Of 1" Diam. Holes Per Ft. Of Inlet
5	25
6	30
8	40
10	50
12	60

3. The below ground portion of the inlet, may be perforated with holes 5/16 inch diameter or less, to provide drainage around the inlet.
4. The tee or elbow diameter must be equal to or larger than the diameter of the conduit downstream from inlet.
5. Install a reducer immediately above the tee or elbow if the inlet diameter is greater than the diameter of the tee or elbow.
6. The underground outlet conduit, must be installed deep enough to provide a minimum 24" of cover (after construction) to prevent crushing.
7. The trash guard for Type II inlets shall be securely fastened to the inlet. Trash guards may be fabricated from metal rods (1/8" diameter or larger) or galvanized welded wire fabric (16 gage or larger). The spacing between vertical members should be 1 inch.

NOTES:

1. The immediate land area around the inlet should be relatively flat (less than 1% slope) and located so that the accumulated sediment can be easily removed.
2. The inside edge of the bales shall be a maximum of 2 feet from the edge of the inlet.
3. Filter fabric shall meet the requirements of material specification 592 GEOTEXTILE Table 1 or 2, Class 1 with AOS of at least 30 for nonwoven and 50 for woven.
4. Anchors shall be rebar, steel pickets or 2" x 2" stakes, and shall be long enough to extend at least 1.5 to 2.0 feet into the ground when the top is flush with the bale.

NOTES:

1. There are no riser height restrictions as long as the riser is located in compacted earth fill.
2. The corrugated metal riser with 4 feet conduit stub shall be fabricated from galvanized steel or aluminum. If fabricated from steel, any zinc coating damaged by welding shall be repaired as follows:
 - A) All loose and cracked coating shall be removed by wire brushing and all dirt and greasy material by a suitable solvent.
 - B) The damaged area shall be painted with two coats of Zinc Dust-Zinc Oxide primer, followed by a heavy coat of Fibrated Asphalt Mastic.
3. The angles and anti-vortex baffle plate shall be fabricated from the same material as the riser to which they will be attached. If fabricated from steel, the angles and anti-vortex baffle plate shall be galvanized after cutting and drilling.
4. The anti-vortex baffle plate can be left square, if all corners are rounded with a 6 inch radius.
5. All bolts, nuts and washers shall be galvanized steel.
6. Corrugated aluminum risers and conduits shall be separated from the reinforced concrete base by at least 2 layers of plastic tape with a total thickness of at least 24 mils or by a heavy coat of Alkali-Resistant Bituminous paint.

CORRUGATED METAL PIPE DIAPHRAGM

Flat Sheet Metal Diaphragm Shall Be Cut To Fit Corrugations Of Helical Band And Welded With A Continuous Weld.

Size And Spacing Of Slotted Openings Shall Be The Same As Shown For C.M. Diaphragms.

NOTE: For Details of Fabrication Dimensions, Slotted Holes And Notes, See Notes And Dimension Table Shown On Sheet 2.

PARTIAL ELEVATION

ISOMETRIC VIEW

DETAILS OF HELICAL PIPE DIAPHRAGMS

NOTES:

1. Materials and coatings for all diaphragms shall be the same as that specified for the pipe.
2. Diaphragms shall be shop fabricated, assembled and marked by painting to identify matching half sections of each diaphragm.
3. The laps between the half sections and between the pipe and connecting bands shall be caulked with fibrated asphalt mastic at the time of installation.
4. All tank lugs, rods and nuts shall be galvanized steel. Where aluminum diaphragms are used, the rods and lugs shall be separated from the aluminum bands by at least two (2) layers of 2" wide plastic tape with a total thickness of 24 mils or more.
5. The diaphragms shall be welded to the connecting bands as shown on the drawings. All welds and damaged galvanized metal shall be cleaned and painted with 2 coats of zinc dust-zinc oxide primer. (Fed Spec TT-P-641 Type III)
6. Bands shall be fabricated from material having the same class of corrugation as the pipe to which it is to be attached.

NOTES:

1. SDR 26 pressure rated PVC pipe shall conform to ASTM standard D-2241. Schedule 40 and 80 PVC shall conform to ASTM standard D-1785.
2. Pipe material designation shall be PVC 1120 OR PVC 1220.
3. The longest section of pipe in the installation shall not exceed 20 ft. in length.
4. PVC pipe shall be joined by double gasketed couplings capable of withstanding 160 PSI internal pressure. Minimum length of coupling shall be 7.8" for 6" dia., 8.2" for 8" dia., 9.1" for 10" dia and 10" for 12" dia.
5. PVC solvent cement shall be formulated for the intended use to produce a weld of maximum strength.
6. Pipe must be manufactured from ultra-violet decay resistant material. Areas of pipe that will be exposed after installation is completed must be further protected from ultra-violet degradation. Wrapping the exterior of exposed pipe with plastic tape or by painting is acceptable.
7. The pipe shall be firmly and uniformly bedded so the lower one-sixth of the circumference will bear against original or compacted earth.

SECTION A-A

NOTES:

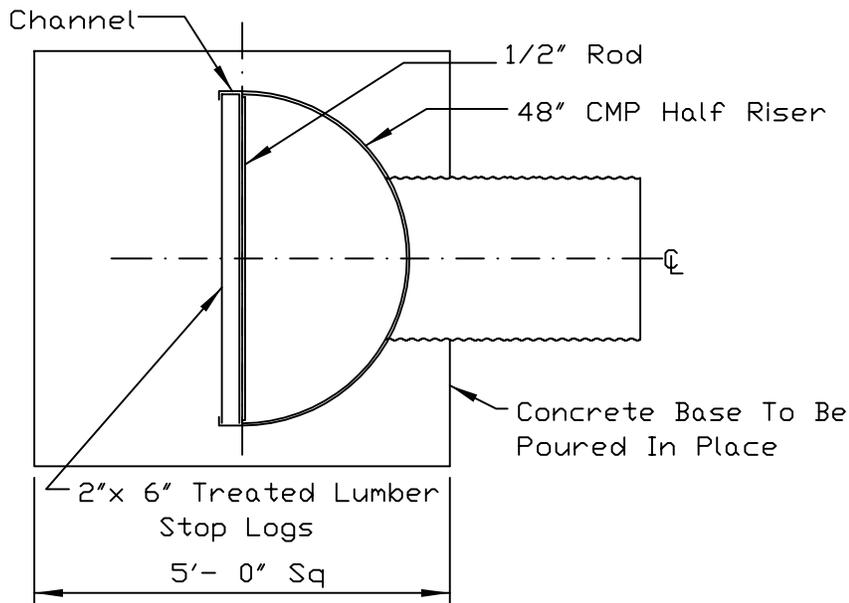

1. Helical pipe shall have a mastic sealer applied at the collar location. The sealer will not be required for PVC or annular pipe.
2. The center membrane section may be 1/16 inch gum rubber, butyl rubber or neoprene. The entire antiseep may be made of these materials.
3. The outer portion of the antiseep collar, away from the pipe, may be made of a minimum 20 mil plastic sheet.
4. Cut a hole, 3 inches smaller than the diameter of the pipe, centered on the material used at the pipe and force it over the end of the pipe.
5. The antiseep material shall be fastened to the pipe using a stainless steel clamp.
6. Completed installation must be watertight.
7. Care must be taken to back fill equally on both sides of the antiseep collar.

Number Of 2"X 6" Stop Logs (Approximate Length 48")	

NOTES:

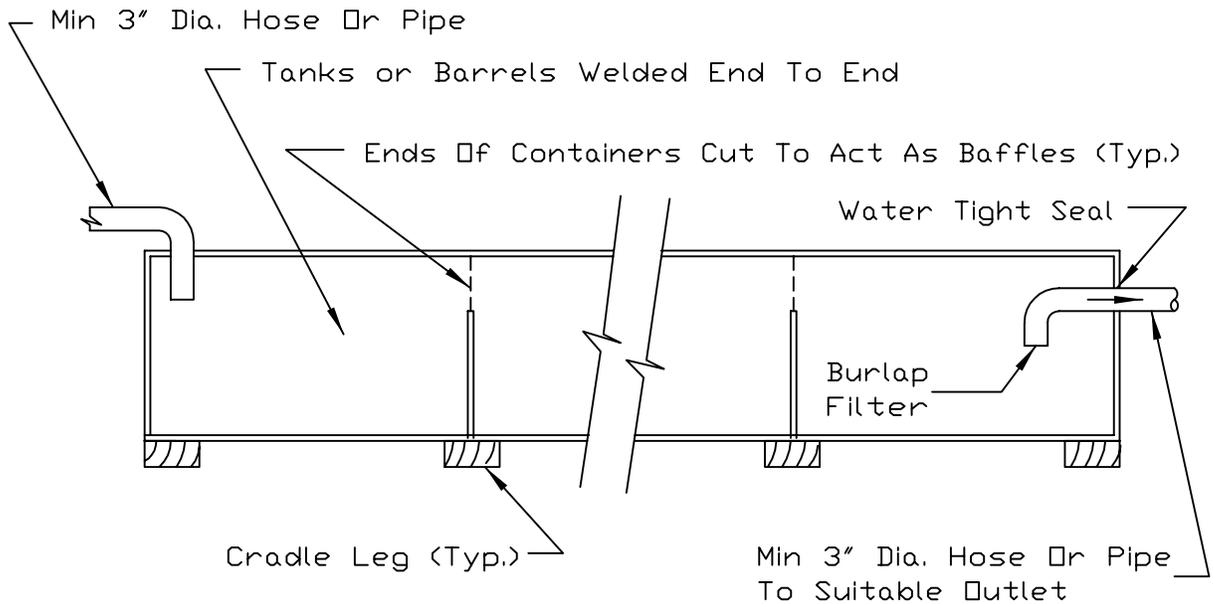

1. The riser height shall be limited to 5 feet.
2. The conduit diameter shall be limited to 12" thru 27".
3. The corrugated metal riser with 4 feet conduit stub shall be fabricated from galvanized steel or aluminum. If fabricated from steel, any zinc coating damaged by welding shall be repaired as follow:
 - A) All loose and cracked coating shall be removed by wire brushing and all dirt and greasy material by a suitable solvent.
 - B) The damaged area shall be painted with two coats of Zinc Dust-Zinc Oxide Primer, follow by a heavy coat of Fibrated Asphalt Mastic.
4. Corrugated aluminum risers and conduits shall be separated from the reinforced concrete base by at least 2 layers of plastic tape with a total thickness of at least 24 mils or by a heavy coat of Alkali-Resistant Bituminous paint.

RIGHT OF WAY DIVERSION PLAN

TYPICAL GRAVEL STRUCTURE

TYPICAL EARTHEN STRUCTURE

NOTES:

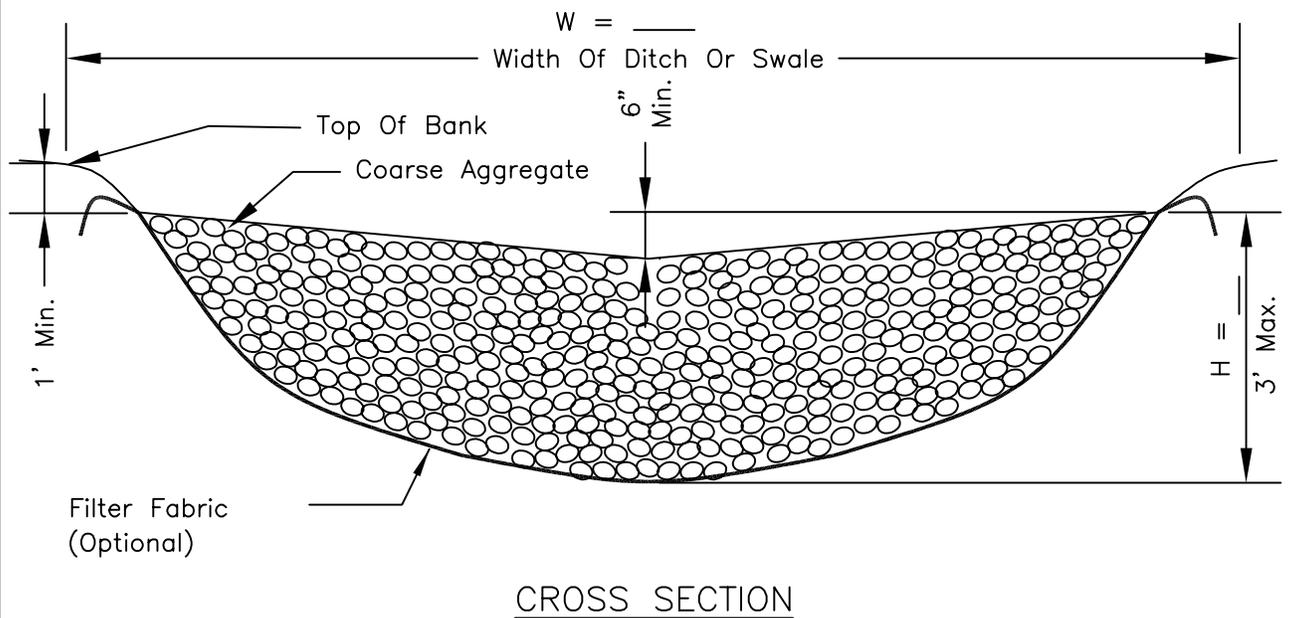

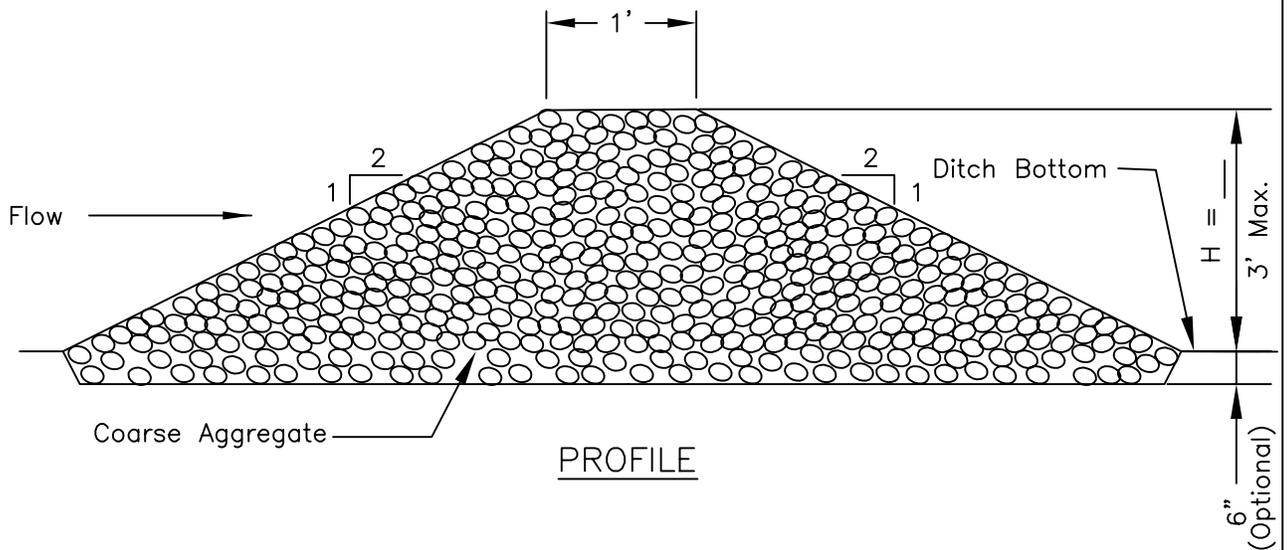

1. Install the diversion as soon as right-of-way has been cleared and graded.
2. Disc the base for the constructed ridge before placing fill.
3. Track the ridge to compact it to the design cross section.
4. Locate the outlet on an undisturbed area. Adjust field spacing of the diversion to use the most stable outlet areas. When natural areas are not deemed satisfactory, provide outlet protection.
5. Immediately seed and mulch the portions of the diversions not subject to construction traffic. Stabilize with gravel areas to be crossed by vehicles.
6. Coarse aggregate, if used, shall meet one of the following IDOT gradations: CA-1, CA-2, CA-3, OR CA-4.

SUMP PIT PLAN

NOTES:

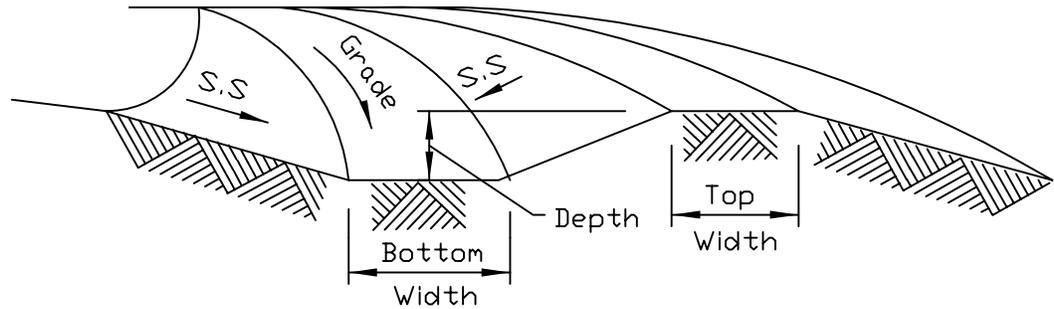

1. Pit dimensions are optional.
2. The standpipe will be constructed by perforating a 12"-24" diameter corrugated metal or PVC pipe.
3. A base of 2" aggregate will be placed in the pit to a minimum depth of 12". After installing the standpipe, the pit surrounding the standpipe will then be backfilled with 2" aggregate.
4. The standpipe will extend 12" to 18" above the lip of the pit.
5. If discharge will be pumped directly to a storm drainage system, the standpipe will be wrapped with filter fabric before installation.
6. If desired, 1/4"-1/2" hardware cloth may be placed around the standpipe prior to attaching the filter fabric. This will increase the rate of water seepage into the pipe.

PLANTING PROCEDURE FOR BALLED AND BURLAPPED OR CONTAINER GROWN TREES AND SHRUBS

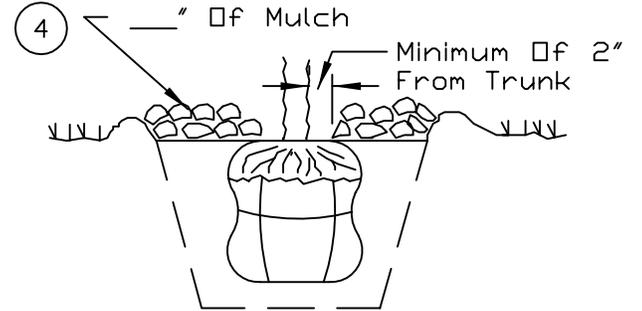

Add enough tamped soil in the bottom of the hole to set the ball at or slightly higher than the original planting depth.

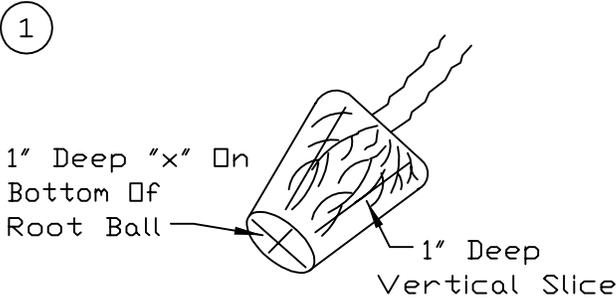

Fill the hole 3/4 full of tamped soil then remove all exposed burlap and twine using a sharp utility knife.

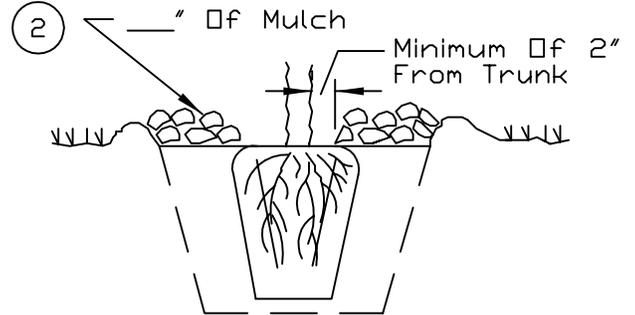

Fill the remaining 1/4 of the hole with water to remove air pockets and settle the soil. Finish filling the hole with soil after all the water has drained.

Unless soil is poorly drained, mound soil around edges of hole 4" to 6" high. Add a minimum of 4" of approved mulching material. Keep mulch about 2" from tree trunk.

Cut the circling roots of container grown trees with a sharp utility knife. Make 4 vertical slices on the sides and an "x" on the bottom. All slices should be 1-inch in depth.

Plant container-grown trees using same steps as for B & B trees except that the plastic container should be completely removed.

SECTION 8 - PRACTICE EVALUATION

INTRODUCTION

This section provides information on the effects of urban conservation practices on Soil, Water, Air, Plant and Animal (SWAPA) resources within the urban ecosystem.

Urban resource planning cannot be properly completed without considering the interrelationships of the SWAPA resources within the urban ecosystem. As the public's concern for the environment, whether urban or rural, increases, the interrelationships of these resources will become more critical as project plans are developed.

Urban Conservation Practices Physical Effects (CPPE) sheets can provide details on the physical effects that specific urban practices have on the SWAPA resources. These, in turn, can be used to guide decisions on the best practices to use as a part of the resource management system needed to address the resource concerns identified for the project. The estimation of the physical effects for a practice is based on professional experience and available technical information.

The key question that should be asked when reviewing the CPPE is, "if this practice is applied, what effect will it have not only on the identified or potential target resource concerns or considerations, but also on all the others contained in the column headings?". The planner needs to recognize the effect of applying urban conservation practices in order to select combinations of practices that solve the identified or potential concerns without creating new problems.

Conservation practice physical effects for new Illinois Urban Manual practice standards prepared since the original 1995 version of the manual have not yet been completed. Once completed this section will be updated.

This section was prepared in August 1994.

NRCS IL August 1994

URBAN CONSERVATION PRACTICE PHYSICAL EFFECTS

RESOURCE

CONTENTS

Soil	Effects of urban practices on the soil resources as these relate to urban soil erosion, soil condition and deposition
Water	Effects of urban practices on the water resources especially as these relate to water quantity and quality
Air	Effects of urban practices on the air resources as these relate to air quality and condition
Plants	Effects of urban practices on the plant resources as these relate to plant suitability, condition and management
Animals	Effects of urban practices on the animal resources as these relate to urban wildlife habitat and management

CONSIDERATIONS:		(1) EROSION					(2) CONDITION			
ASPECTS/ PROBLEMS	PRACTICE	CLASSIC GULLY	STREAMBANK	SOIL MASS MOVEMENT	ROADBANK AND CONSTRUCTION SITES	SHEET AND RILL	SOIL COMPACTION	SOIL CONTAMINANTS		
								EXCESS CHEMICAL CONTENT, SALINITY, SELENIUM, BORON, HEAVY METAL	EXCESS FERTILIZER	EXCESS PESTICIDES
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Gullies are channels that may grow or enlarge from year to year by headcutting and lateral widening. They are too deep to be erased by normal operations.	Sloughing of banks caused by overbank flow, unstable soils, obstructions, unstable channel bottom, or all of these.	Soil slippage, landslides, or slope failure, normally on hillsides, in deep cuts or through unstable soil on sloping land that creates a large volume of soil movement.	The erosion as identified is causing problems and damage, both on-site and off-site.	The movement of soil from water forces, requiring treatment when soil loss tolerance level is exceeded.	Compaction is excess compressing of soil particles and aggregates by machine and natural consolidation, thereby effecting plant-soil-moisture-air relationship.	Excess chemical content, salinity, selenium, boron, heavy metals. Includes the amounts of desirable and undesirable chemical elements and compounds consisting of either organic or inorganic forms and restricts the desired use of soil.	Excess fertilizer occurs if the application of fertilizer or quantity of nutrients restricts the desired use of the soil.	Excess pesticides occur if the application method type or the quantity of the residuals restrict desired use of the soil.
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
800 - Urban Stormwater Wetlands	A constructed system of shallow pools that create growing conditions for wetland plants to lessen the impacts of stormwater quality and quantity in urban areas.	Negligible.	Slight to significant decrease due to establishment of protective riparian vegetation.	Negligible.	Negligible.	Negligible.	Significant decrease due to establishment and management of permanent cover, deposition of organic material, and increased microbial action.	Moderate to significant decrease due to uptake of chemicals by hydrophytes.	Moderate to significant decrease due to uptake of chemicals by hydrophytes.	Moderate to significant decrease due to less pesticide use and some uptake by hydrophytes.
806 - Construction Road Stabilization	The stabilization of temporary construction access routes, subdivision roads, on-site vehicle transportation roads, and construction parking areas with stone immediately after grading.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.
808 - Culvert Inlet Protection	A temporary sediment filter located at the inlet to storm sewer culverts.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.
815 - Diversion	A channel and supporting ridge constructed across the slope to collect and divert runoff.	Slight to significant decrease due to interception of concentrated flow.	Slight to moderate decrease because of reduction in overbank flow.	Negligible to moderate decrease if water is diverted from top of slope.	Moderate to significant decrease due to interception of surface flow.	Negligible to slight decrease if slope length is reduced.	Negligible.	Negligible to slight decrease due to increased infiltration.	Negligible.	Negligible.
820 - Diversion Dike	A dike or dike and channel constructed along the perimeter of a disturbed construction area.	Slight to significant decrease due to interception of concentrated flow.	Slight to moderate decrease because of reduction in overbank flow.	Negligible to moderate decrease if water is diverted from top of slope.	Moderate to significant decrease due to interception of surface flow.	Negligible to slight decrease if slope length is reduced.	Negligible.	Negligible to slight decrease due to increased infiltration.	Negligible.	Negligible.

CONSIDERATIONS:		(3) DEPOSITION							
ASPECTS/ PROBLEMS	PRACTICE		DAMAGE		SAFETY				
			ON-SITE	OFF-SITE	ON-SITE	OFF-SITE			
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION		Vegetation destroyed or structural practices damaged or rendered inoperable due to excessive sediment deposition.	Same as on-site damage.	Deposition on roads and railroads that cause accidents, loss of life, and loss of access for emergency vehicles.	Same as on-site safety.			
PRACTICE CODE AND NAME	OTHER EXPLANATIONS								
800 - Urban Stormwater Wetlands	A constructed system of shallow pools that create growing conditions for wetland plants to lessen the impacts of stormwater quality and quantity in urban areas.		Slight to significant decrease due to establishment of impoundments and hydrophytic plants which trap sediment.	Negligible to significant decrease due to trapping of sediment on site.	Negligible to slight decrease due to establishment of impoundments and hydrophytic plants which trap sediment.	Negligible to significant decrease due to trapping of sediment on site.			
806 - Construction Road Stabilization	The stabilization of temporary construction access routes, subdivision roads, on-site vehicle transportation roads, and construction parking areas with stone immediately after grading.		Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.			
808 - Culvert Inlet Protection	A temporary sediment filter located at the inlet to storm sewer culverts.		Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.			
815 - Diversion	A channel and supporting ridge constructed across the slope to collect and divert runoff.		Slight to significant decrease due to reduced runoff and sedimentation.	Negligible to moderate decrease due to reduced runoff and sedimentation.	Slight to significant decrease due to reduced runoff and sedimentation.	Negligible to moderate decrease due to reduced runoff and sedimentation.			
820 - Diversion Dike	A dike or dike and channel constructed along the perimeter of a disturbed construction area.		Slight to significant decrease due to reduced runoff and sedimentation.	Negligible to moderate decrease due to reduced runoff and sedimentation.	Slight to significant decrease due to reduced runoff and sedimentation.	Negligible to moderate decrease due to reduced runoff and sedimentation.			

CONSIDERATIONS:		(1) EROSION					(2) CONDITION			
ASPECTS/ PROBLEMS	PRACTICE	CLASSIC GULLY	STREAMBANK	SOIL MASS MOVEMENT	ROADBANK AND CONSTRUCTION SITES	SHEET AND RILL	SOIL COMPACTION	SOIL CONTAMINANTS		
								EXCESS CHEMICAL CONTENT, SALINITY, SELENIUM, BORON, HEAVY METAL	EXCESS FERTILIZER	EXCESS PESTICIDES
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Gullies are channels that may grow or enlarge from year to year by headcutting and lateral widening. They are too deep to be erased by normal operations.	Sloughing of banks caused by overbank flow, unstable soils, obstructions, unstable channel bottom, or all of these.	Soil slippage, landslides, or slope failure, normally on hillsides, in deep cuts or through unstable soil on sloping land that creates a large volume of soil movement.	The erosion as identified is causing problems and damage, both on-site and off-site.	The movement of soil from water forces, requiring treatment when soil loss tolerance level is exceeded.	Compaction is excess compressing of soil particles and aggregates by machine and natural consolidation, thereby effecting plant-soil-moisture-air relationship.	Excess chemical content, salinity, selenium, boron, heavy metals. Includes the amounts of desirable and undesirable chemical elements and compounds consisting of either organic or inorganic forms and restricts the desired use of soil.	Excess fertilizer occurs if the application of fertilizer or quantity of nutrients restricts the desired use of the soil.	Excess pesticides occur if the application method type or the quantity of the residuals restrict desired use of the soil.
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
825 - Dust Control	Controlling dust blowing and movement on construction sites and roads.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Negligible to slight increase if runoff occurs.	Negligible to significant increase if water vehicle is used.	Negligible.	Negligible.	Negligible.
830 - Erosion Blanket	The application of a preformed protective blanket of straw or other plant residue, or plastic fibers formed into a mat, usually with a plastic mesh on one or both sides.	Slight unless combined with a vegetative cover seeding.	Slight unless combined with a vegetative cover seeding.	Slight unless combined with a vegetative cover seeding.	Slight unless combined with a vegetative cover seeding.	Moderate to significant decrease because of increased surface cover.	Slight decrease due to protection of soil surface from impact of raindrops.	Negligible.	Negligible.	Negligible.
835 - Filter Strip	A created or preserved area of vegetation designed to remove sediment and other pollutants and to enhance the infiltration of surface water runoff.	Negligible to slight decrease because of water spreading depending on location of filter strip.	Moderate to slight decrease because of decrease of overbank flow.	Negligible.	Negligible to slight decrease because of erosion reduction.	Slight to significant decrease because of reduced erosion on area vegetated.	Slight to significant decrease because of development of root mass and increased organic material within the field border.	Negligible.	Negligible.	Negligible.
840 - Grass-Lined Channel	A natural or constructed channel that is shaped or graded to required dimensions and established with suitable vegetation for stable conveyance of runoff.	Slight to significant decrease because of managed and guided runoff.	Slight to moderate decrease because of managed and guided runoff.	Not applicable.	Negligible to slight decrease because of managed and guided runoff.	Negligible.	Not applicable.	Negligible.	Negligible.	Negligible.
841 - Impoundment Structure-Full Flow	A dam or excavation which creates an impoundment to collect and store debris, sediment, or water.	Negligible to significant decrease due to stabilization if embankment is constructed in gully.	Negligible to slight decrease due to reduced peak flows downstream from impoundment.	Not applicable.	Negligible.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Negligible.

CONSIDERATIONS:		(3) DEPOSITION							
ASPECTS/ PROBLEMS	PRACTICE		DAMAGE		SAFETY				
			ON-SITE	OFF-SITE	ON-SITE	OFF-SITE			
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION		Vegetation destroyed or structural practices damaged or rendered inoperable due to excessive sediment deposition.	Same as on-site damage.	Deposition on roads and railroads that cause accidents, loss of life, and loss of access for emergency vehicles.	Same as on-site safety.			
PRACTICE CODE AND NAME	OTHER EXPLANATIONS								
825 - Dust Control	Controlling dust blowing and movement on construction sites and roads.		Negligible to slight decrease if volume of water applied is controlled to prevent excess runoff.	Same as on-site damage.	Negligible to slight decrease if volume of water applied is controlled to prevent excess runoff.	Same as on-site safety.			
830 - Erosion Blanket	The application of a preformed protective blanket of straw or other plant residue, or plastic fibers formed into a mat, usually with a plastic mesh on one or both sides.		Moderate to significant decrease due to protection of soil surface from impact of raindrops.	Moderate to significant decrease due to protection of soil surface from impact of raindrops.	Moderate to significant decrease due to protection of soil surface from impact of raindrops.	Moderate to significant decrease due to protection of soil surface from impact of raindrops.			
835 - Filter Strip	A created or preserved area of vegetation designed to remove sediment and other pollutants and to enhance the infiltration of surface water runoff.		Slight to significant decrease because of trapping of sediment in filter.	Slight to significant decrease because of trapping of sediment in filter.	Slight to moderate decrease because of trapping of sediment upslope from roads.	Slight decrease because of trapping of sediment upslope from roads.			
840 - Grass-Lined Channel	A natural or constructed channel that is shaped or graded to required dimensions and established with suitable vegetation for stable conveyance of runoff.		Negligible to slight decrease due to managed runoff and reduced sedimentation.	Same as on-site damage.	Negligible to slight decrease due to managed runoff and reduced sedimentation.	Same as on-site safety.			
841 - Impoundment Structure-Full Flow	A dam or excavation which creates an impoundment to collect and store debris, sediment, or water.		Slight to significant decrease due to sediment deposition in impoundment.	Same as on-site damage.	Slight to significant decrease due to sediment deposition in impoundment.	Same as on-site safety.

TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION									
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
842 - Impoundment Structure-Routed	A dam or excavation which creates an impoundment to collect and store debris, sediment, or water.	Negligible to significant decrease due to stabilization if embankment is constructed in gully.	Negligible to slight decrease due to reduced peak flows downstream of impoundment.	Not applicable.	Negligible.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Negligible.
847 - Infiltration Trench	An excavated trench filled with coarse granular material in which stormwater runoff is collected for temporary storage and infiltration.	Slight to significant decrease due to interception of concentrated flow.	Negligible to slight decrease due to reduced peak flow.	Slight to moderate increase if located above a potential soil mass movement site.	Negligible to slight decrease due to reduced peak flows.	Slight to moderate decrease due to reduced overland flow.	Negligible.	Not applicable.	Not applicable.	Not applicable.
850 - Inlet Protection - Block and Gravel	A sediment control barrier formed around a storm drain inlet by the use of standard concrete blocks and gravel.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.
855 - Inlet Protection - Excavated Drain	An excavated area in the approach to a storm drain drop inlet or curb inlet.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.
860 - Inlet Protection - Fabric Drop	A temporary fabric barrier placed around a drop inlet.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.

ASPECTS/ PROBLEMS	PRACTICE	CLASSIC GULLY	STREAMBANK	SOIL MASS MOVEMENT	ROADBANK AND CONSTRUCTION SITES	SHEET AND RILL	SOIL COMPACTION	SOIL CONTAMINANTS		
								EXCESS CHEMICAL CONTENT, SALINITY, SELENIUM, BORON, HEAVY METAL	EXCESS FERTILIZER	EXCESS PESTICIDES
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Gullies are channels that may grow or enlarge from year to year by headcutting and lateral widening. They are too deep to be erased by normal operations.	Sloughing of banks caused by overbank flow, unstable soils, obstructions, unstable channel bottom, or all of these.	Soil slippage, landslides, or slope failure, normally on hillsides, in deep cuts or through unstable soil on sloping land that creates a large volume of soil movement.	The erosion as identified is causing problems and damage, both on-site and off-site.	The movement of soil from water forces, requiring treatment when soil loss tolerance level is exceeded.	Compaction is excess compressing of soil particles and aggregates by machine and natural consolidation, thereby effecting plant-soil-moisture-air relationship.	Excess chemical content, salinity, selenium, boron, heavy metals. Includes the amounts of desirable and undesirable chemical elements and compounds consisting of either organic or inorganic forms and restricts the desired use of soil.	Excess fertilizer occurs if the application of fertilizer or quantity of nutrients restricts the desired use of the soil.	Excess pesticides occur if the application method type or the quantity of the residuals restrict desired use of the soil.
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
935 - Straw Bale Barrier	A temporary barrier of entrenched and anchored straw bales used to intercept sediment-laden runoff from small drainage areas of disturbed soil.	Not applicable.	Not applicable.	Not applicable.	Slight to significant decrease in off-site damage due to retention of trapped sediment.	Negligible.	Not applicable.	Not applicable.	Not applicable.	Not applicable.
940 - Structural Streambank Stabilization	Stabilization of eroding streambanks by use of designed structural measures.	Negligible.	Significant decrease due to stabilizing banks.	Significant decrease along unstable areas due to stabilization of the toe slope that was undermining the mass movement area.	Not applicable.	Negligible.	Not applicable.	Not applicable.	Not applicable.	Not applicable.
945 - Subsurface Drain	A conduit, such as corrugated plastic tubing, tile, or pipe, installed beneath the ground surface to collect and/or convey drainage water.	Slight decrease due to intercepting subsurface water moving laterally into gully.	Slight decrease due to intercepting water exiting to streambank.	Moderate to significant decrease due to removal of subsurface water which contributes to the instability of soil mass.	Moderate to significant decrease due to intercepting water that exits on roadbanks.	Negligible to slight decrease because of increased infiltration.	Slight to moderate decrease because excess water is removed from the soil profile.	Significant decrease in excess chemicals because water is used to leach out salts and sodium.	Significant decrease due to leaching of water soluble contaminants.	Significant decrease due to leaching of water soluble contaminants.
950 - Sump Pit	A temporary pit constructed to trap and filter water for pumping into a suitable discharge area.	Not applicable.	Not applicable.	Negligible to slight decrease due to removal of ponded water at the toe slope of excavations that undermines the mass movement area.	Negligible to slight decrease in off-site damage due to the filtering of sediment-laden water.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.
953 - Surface Roughening	A rough soil surface with horizontal grooves running across the slope on the contour, stair stepping, or tracking with construction equipment.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.

PRACTICE CODE AND NAME	OTHER EXPLANATIONS										
935 - Straw Bale Barrier	A temporary barrier of entrenched and anchored straw bales used to intercept sediment-laden runoff from small drainage areas of disturbed soil.		Vegetation destroyed or structural practices damaged or rendered inoperable due to excessive sediment deposition.	Slight to significant decrease due to retention of trapped sediment.	Moderate to significant decrease due to retention of trapped sediment.	Deposition on roads and railroads that cause accidents, loss of life, and loss of access for emergency vehicles.	Same as on-site safety.				
940 - Structural Streambank Stabilization	Stabilization of eroding streambanks by use of designed structural measures.		Negligible to slight decrease due to limited area impacted.	Moderate to significant decrease because erosion provided high sediment delivery directly to stream system and in high water stages deposits on flood plain.	Negligible to slight decrease due to limited area impacted.	Slight to significant decrease due to reduced deposition in water courses that creates safety problem.					
945 - Subsurface Drain	A conduit, such as corrugated plastic tubing, tile, or pipe, installed beneath the ground surface to collect and/or convey drainage water.		Negligible to slight decrease due to managed runoff and reduced sediment.	Same as on-site damage.	Negligible to slight decrease due to managed runoff and reduced sediment.	Same as on-site safety.					
950 - Sump Pit	A temporary pit constructed to trap and filter water for pumping into a suitable discharge area.		Negligible to slight decrease due to the filtering of sediment-laden water.	Slight to moderate decrease due to the filtering of sediment-laden water.	Negligible to slight decrease due to the filtering of sediment-laden water.	Slight to moderate decrease due to the filtering of sediment-laden water.					
953 - Surface Roughening	A rough soil surface with horizontal grooves running across the slope on the contour, stair stepping, or tracking with construction equipment.		Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.

PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
955 - Temporary Diversion	A temporary ridge or excavated channel or combination ridge and channel constructed across sloping land on a predetermined grade.	Slight to significant decrease due to the interception of concentrated flow.	Negligible due to reduction in overbank flow.	Negligible to moderate decrease if water is diverted from top of slope.	Moderate to significant decrease due to interception of surface flow.	Negligible to slight decrease if slope length is reduced.	Negligible.	Negligible to slight decrease due to increased infiltration.	Negligible.	Negligible.
960 - Temporary Sediment Trap	A small temporary ponding basin formed by construction of an embankment or excavated basin.	Slight to significant decrease below basin depending on storage available and area controlled.	Slight to significant decrease below basin depending on storage available and area controlled.	Potential for slight increase because of increased infiltration depending on location of basin.	Slight to significant decrease below the basin because of reduced bedloads and/or reduced flows depending on storage available and area controlled.	Negligible.	Short-term increase in area of construction.	Negligible.	Negligible.	Negligible.
965 - Temporary Seeding	Planting rapid-growing annual grasses or small grains to provide initial, temporary coverage for erosion control on disturbed areas.	Slight decrease because of vegetative cover and reduced runoff.	Moderate to slight decrease because of vegetative cover and reduced runoff.	Negligible.	Significant decrease because of vegetative cover, improved root mass, and reduced runoff.	Slight to significant decrease because of vegetative cover.	Slight to moderate decrease because of vegetative cover.	Negligible to slight decrease because of plant uptake and increased infiltration.	Not applicable.	Not applicable.
970 - Temporary Slope Drain	A flexible tubing or rigid conduit extending temporarily from the top to the bottom of a cut or fill slope.	Negligible.	Negligible.	Negligible to slight decrease due to managed and guided runoff.	Negligible to slight decrease due to managed and guided runoff.	Not applicable.	Negligible.	Not applicable.	Not applicable.	Not applicable.
975 - Temporary Stream Crossing	A bridge, ford, or temporary structure installed across a stream or watercourse for short-term use by construction vehicles or heavy equipment.	Not applicable.	Slight to moderate decrease due to temporary stabilization of streambanks.	Negligible to slight decrease depending on location of crossing in relation to mass movement area.	Slight to moderate decrease due to temporary stabilization of streambanks.	Negligible.	Negligible to slight increase depending on size and type of equipment used to install crossing.	Not applicable.	Not applicable.	Not applicable.

		SEEPS	RUNOFF/FLOODING	EXCESS SUBSURFACE WATER		ON-SITE	OFF-SITE	WATER BODIES, STREAMS, LAKES		
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Subsurface water flows onto the surface of the land.	Water accumulates on the surface of the land.	Subsurface water accumulates in the soil profile, which adversely affects plant growth and production operations.		Water quantity that affects drainage ditches, road ditches, culverts, and canals.	Water quantity that affects drainage ditches, road ditches, culverts, and canals.	Water quantity that is affected because of the loss of storage capacity as well as the loss of conveyance capacity.		
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
800 - Urban Stormwater Wetlands	A constructed system of shallow pools that create growing conditions for wetland plants to lessen the impacts of stormwater quality and quantity in urban areas.	Significant decrease because of water management if seep is incorporated in constructed wetland. Slight to significant increase if seep develops downstream of constructed wetland or if existing seep is managed as wetland.	Slight to moderate decrease because of increased water storage area relative to runoff quantity.	Negligible to moderate increase because of water management dependent on extent of impoundment creation and management.		Slight to significant decrease because of increased hydrophytic vegetation and impounded water will reduce erosion and sedimentation.	Slight to moderate decrease because of increased hydrophytic vegetation and impounded water will reduce erosion and sedimentation.	Slight to moderate decrease because of increased hydrophytic vegetation and impounded water will reduce erosion and sedimentation.		
806 - Construction Road Stabilization	The stabilization of temporary construction access routes, subdivision roads, on-site vehicle transportation roads, and construction parking areas with stone immediately after grading.	Not determined yet.	Not determined yet.	Not determined yet.		Not determined yet.	Not determined yet.	Not determined yet.		
808 - Culvert Inlet Protection	A temporary sediment filter located at the inlet to storm sewer culverts.	Not determined yet.	Not determined yet.	Not determined yet.		Not determined yet.	Not determined yet.	Not determined yet.		
815 - Diversion	A channel and supporting ridge constructed across the slope to collect and divert runoff.	Slight decrease because of protection of down slope areas.	Significant decrease because of protection of area below diversion.	Negligible.		Slight to significant decrease because of decreased sediment load, and because of proximity and control of ephemeral gullies and other erosion sources.	Negligible to moderate decrease because of decreased sediment load.	Negligible to slight decrease because of decreased sediment load.		
820 - Diversion Dike	A dike or dike and channel constructed along the perimeter of a disturbed construction area.	Negligible to moderate increase because of temporary storage within dike area.	Moderate to significant decrease because of decreased flooding.	Negligible.		Negligible to significant decrease because of flood water management.	Negligible to significant decrease because of flood water management.	Negligible to significant decrease because of flood water management.

		PESTICIDES	NUTRIENTS AND ORGANICS	HEAVY METALS	PESTICIDES	NUTRIENTS AND ORGANICS	SUSPENDED SEDIMENT AND TURBIDITY	SALINITY	HEAVY METALS	PATHOGENS
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Water pollution problems from pesticides. Pesticide means "all" chemicals used to manage weeds, insects, and diseases.	Water pollution problems from natural or human-induced common nutrients of N, P, K, Ca, Na, and Mg.	Water pollution problems from natural and human-induced common metals or metal compounds, such as iron, lead, zinc, copper, and cobalt.	Surface water pollution problems from pesticides. Pesticide means "all" chemicals used to manage weeds, insects, and diseases.	Surface water pollution problems that result from the use of all applied plant nutrients with emphasis on phosphorus and total organic carbon.	Water pollution suspended sediment and turbidity. Suspended sediment is sediment held in surrounding fluid. Turbidity is reduced clarity of fluids because of presence of suspended matter.	Water pollution from common salts such as sodium, calcium, boron and selenium.	Water pollution from natural and human-induced common metals and metal compounds, such as iron, lead, zinc, copper, and cobalt.	Water pollution from bacteria, viruses, protozoans, helminths, and fungi. Pathogens can be transported in both fluid and particulate forms.
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
800 - Urban Stormwater Wetlands	A constructed system of shallow pools that create growing conditions for wetland plants to lessen the impacts of stormwater quality and quantity in urban areas.	Negligible to moderate decrease because habitat reduces need for use of chemicals and increased vegetation will uptake pesticides.	Negligible to moderate decrease because wetland management reduces need to add nutrients and uptake of nutrients by hydrophytes.	Negligible to slight decrease because of uptake of heavy metals by hydrophytes.	Moderate to significant decrease because permanent habitat reduces need to use chemicals. Hydrophytes will uptake pesticides. Impoundments will reduce runoff and transport of pesticides.	Moderate to significant decrease because permanent habitat reduces need to use chemicals. Hydrophytes will uptake pesticides. Impoundments will reduce runoff and transport of nutrients and organics.	Moderate to significant decrease because impoundments and hydrophytes will trap sediment.	Moderate to significant decrease because hydrophytes will uptake salts and reduce runoff and transport of salinity.	Moderate to significant decrease because hydrophytes will uptake heavy metals and reduce runoff and transport of heavy metals.	Slight to moderate decrease because of increased assimilation of pathogens in wetland and reduced runoff and transport of pathogens.
806 - Construction Road Stabilization	The stabilization of temporary construction access routes, subdivision roads, on-site vehicle transportation roads, and construction parking areas with stone immediately after grading.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.
808 - Culvert Inlet Protection	A temporary sediment filter located at the inlet to storm sewer culverts.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.
815 - Diversion	A channel and supporting ridge constructed across the slope to collect and divert runoff.	Slight increase because of increased infiltration of soluble pesticides.	Slight increase because of increased infiltration of solubles, such as nitrate nitrogen.	Negligible.	Slight decrease because of decrease in sediment bound pesticides. Slight increase in solubles off-site because of increased concentrated flow.	Slight to moderate decrease because of decrease in sediment bound phosphorus and total organic carbon. Slight increase in off-site solubles because of increased concentrated flow.	Slight decrease because of reduced sediment yield.	Negligible.	Negligible to moderate decrease because of managed runoff. Could be significant decrease if diversion is placed above a contaminant waste source with metals.	Negligible to moderate decrease because of managed runoff. Could be significant decrease if diversion is placed above a contaminant waste source with pathogens.
820 - Diversion Dike	A dike or dike and channel constructed along the perimeter of a disturbed construction area.	Negligible.	Negligible.	Negligible.	Slight to moderate decrease because of flood water management.	Slight to moderate decrease because of flood water management.	Slight to moderate decrease because of flood water management.	Negligible.	Negligible.	Slight to moderate decrease because of flood water management.

		SEEPS	RUNOFF/FLOODING	EXCESS SUBSURFACE WATER	ON-SITE	OFF-SITE	WATER BODIES, STREAMS, LAKES			
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Subsurface water flows onto the surface of the land.	Water accumulates on the surface of the land.	Subsurface water accumulates in the soil profile, which adversely affects plant growth and production operations.		Water quantity that affects drainage ditches, road ditches, culverts, and canals.	Water quantity that affects drainage ditches, road ditches, culverts, and canals.	Water quantity that is affected because of the loss of storage capacity as well as the loss of conveyance capacity.		
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
825 - Dust Control	Controlling dust blowing and movement on construction sites and roads.	Not applicable.	Negligible.	Negligible.		Negligible to slight increase if materials applied enter small conveyance or cause runoff which includes sediment.	Negligible.	Not applicable.		
830 - Erosion Blanket	The application of a preformed protective blanket of straw or other plant residue, or plastic fibers formed into a mat, usually with a plastic mesh on one or both sides.	Negligible to slight increase because of increased infiltration.	Slight to moderate decrease because of increased infiltration.	Negligible to slight increase due to more surface water infiltration.		Negligible to slight decrease due to more surface water infiltration and reduced sediment load in runoff water.	Negligible to slight decrease due to reduced sediment load.	Negligible.		
835 - Filter Strip	A created or preserved area of vegetation designed to remove sediment and other pollutants and to enhance the infiltration of surface water runoff.	Negligible to slight increase because of temporary storage within filter area.	Not applicable.	Negligible.		Slight to significant decrease because of reduced sediment transport.	Slight to moderate decrease because of reduced sediment transport.	Slight to moderate decrease because of reduced sediment transport.		
840 - Grass-Lined Channel	A natural or constructed channel that is shaped or graded to required dimensions and established with suitable vegetation for stable conveyance of runoff.	Negligible.	Moderate to significant decrease because of providing stable outlet.	Negligible.		Slight to moderate decrease because of decreased sediment loads by treating the eroding drainageway.	Moderate to significant decrease because of decreased sediment loads.	Slight to moderate decrease because of decreased sediment loads.		
841 - Impoundment Structure-Full Flow	A dam or excavation which creates an impoundment to collect and store debris, sediment, or water.	Slight to moderate increase because of increased infiltration especially during the dormant season.	Slight to moderate decrease because of reduced runoff and increased infiltration depending on watershed characteristics, such as soils, climate, plant communities, and topography.	Slight increase because of increased infiltration.		Moderate to significant decrease because of decreased sediment load.	Moderate to significant decrease because of decreased sediment load.	Moderate to significant decrease because of decreased sediment load.

841 - Impoundment Structure-Full Flow	A dam or excavation which creates an impoundment to collect and store debris, sediment, or water.	Negligible to slight increase if chemical treatment of a pond is used.	Negligible to slight increase because of wildlife use.	Negligible.	Negligible to moderate increase if chemical treatment of a pond is used.	Negligible to moderate increase because of wildlife use.	Negligible.	Not applicable.	Negligible.	Negligible to moderate increase because of aquatic animal feed and feces and products of vegetative decay.

CONSIDERATIONS:		(1) QUANTITY								
ASPECTS/ PROBLEMS	PRACTICE	EXCESS AMOUNTS				RESTRICTED CAPACITY FROM SEDIMENT DEPOSITION IN SMALL CONVEYANCE		RESTRICTED CAPACITY FOR SEDIMENT DEPOSITION		
		SEEPS	RUNOFF/FLOODING	EXCESS SUBSURFACE WATER		ON-SITE	OFF-SITE			
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Subsurface water flows onto the surface of the land.	Water accumulates on the surface of the land.	Subsurface water accumulates in the soil profile, which adversely affects plant growth and production operations.		Water quantity that affects drainage ditches, road ditches, culverts, and canals.	Water quantity that affects drainage ditches, road ditches, culverts, and canals.	Water quantity that is affected because of the loss of storage capacity as well as the loss of conveyance capacity.		
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
842 - Impoundment Structure-Routed	A dam or excavation which creates an impoundment to collect and store debris, sediment, or water.	Slight to moderate increase because of increased infiltration especially during the dormant season.	Slight to moderate decrease because of reduced runoff and increased infiltration depending on watershed characteristics, such as soils, climate, plant communities, and topography.	Slight increase because of increased infiltration.		Moderate to significant decrease because of decreased sediment load.	Moderate to significant decrease because of decreased sediment load.	Moderate to significant decrease because of decreased sediment load.		
847 - Infiltration Trench	An excavated trench filled with coarse granular material in which stormwater runoff is collected for temporary storage and infiltration.	Slight to moderate increase because of increased infiltration.	Slight to significant decrease in flooding due to temporary storage of stormwater runoff.	Slight to moderate increase because of increased infiltration.		Slight decrease due to trapping of sediment in pits or trenches from collection and temporary storage of runoff water.	Slight decrease due to trapping of sediment in pits or trenches from collection and temporary storage of runoff water.	Slight decrease due to trapping of sediment in pits or trenches from collection and temporary storage of runoff water.		
850 - Inlet Protection - Block and Gravel	A sediment control barrier formed around a storm drain inlet by the use of standard concrete blocks and gravel.	Not applicable.	Slight to moderate increase due to ponding around the inlet.	Not applicable.		Slight decrease due to trapping in barrier around storm drain inlet.	Slight decrease due to trapping in barrier around storm drain inlet.	Slight decrease due to trapping in barrier around storm drain inlet.		
855 - Inlet Protection - Excavated Drain	An excavated area in the approach to a storm drain drop inlet or curb inlet.	Not applicable.	Slight to moderate increase due to ponding around the inlet.	Not applicable.		Slight decrease due to trapping of sediments in the excavated area in approach to storm drain.	Slight decrease due to trapping of sediments in the excavated area in approach to storm drain.	Slight decrease due to trapping of sediments in the excavated area in approach to storm drain.		
860 - Inlet Protection - Fabric Drop	A temporary fabric barrier placed around a drop inlet.	Not applicable.	Slight to moderate increase due to ponding around the inlet.	Not applicable.		Slight decrease due to trapping of sediments in barrier around storm drain inlet.	Slight decrease due to trapping of sediments in barrier around storm drain inlet.	Slight decrease due to trapping of sediments in barrier around storm drain inlet.		

CONSIDERATIONS:		(2) QUALITY								
ASPECTS/ PROBLEMS	PRACTICE	GROUND WATER CONTAMINANTS			SURFACE WATER CONTAMINANTS					
		PESTICIDES	NUTRIENTS AND ORGANICS	HEAVY METALS	PESTICIDES	NUTRIENTS AND ORGANICS	SUSPENDED SEDIMENT AND TURBIDITY	SALINITY	HEAVY METALS	PATHOGENS
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Water pollution problems from pesticides. Pesticide means "all" chemicals used to manage weeds, insects, and diseases.	Water pollution problems from natural or human-induced common nutrients of N, P, K, Ca, Na, and Mg.	Water pollution problems from natural and human-induced common metals or metal compounds, such as iron, lead, zinc, copper, and cobalt.	Surface water pollution problems from pesticides. Pesticide means "all" chemicals used to manage weeds, insects, and diseases.	Surface water pollution problems that result from the use of all applied plant nutrients with emphasis on phosphorus and total organic carbon.	Water pollution suspended sediment and turbidity. Suspended sediment is sediment held in surrounding fluid. Turbidity is reduced clarity of fluids because of presence of suspended matter.	Water pollution from common salts such as sodium, calcium, boron and selenium.	Water pollution from natural and human-induced common metals and metal compounds, such as iron, lead, zinc, copper, and cobalt.	Water pollution from bacteria, viruses, protozoans, helminths, and fungi. Pathogens can be transported in both fluid and particulate forms.
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
842 - Impoundment Structure-Routed	A dam or excavation which creates an impoundment to collect and store debris, sediment, or water.	Negligible to slight increase if chemical treatment of a pond is used.	Negligible to slight increase because of wildlife use.	Negligible. TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Subsurface water flows onto the surface of the land.	Water accumulates on the surface of the land.	Subsurface water accumulates in the soil profile, which adversely affects plant growth and production operations.		Water quantity that affects drainage ditches, road ditches, culverts, and canals.	Water quantity that affects drainage ditches, road ditches, culverts, and canals.	Water quantity that is affected because of the loss of storage capacity as well as the loss of conveyance capacity.		
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
955 - Temporary Diversion	A temporary ridge or excavated channel or combination ridge and channel constructed across sloping land on a predetermined grade.	Slight decrease because of protection of down slope areas.	Moderate decrease because of protection of area below diversion.	Negligible.		Slight to significant decrease because of decreased sediment load, because of proximity and control of ephemeral gullies and other erosion sources.	Negligible to moderate decrease because of decreased sediment load.	Negligible to slight decrease because of decreased sediment load.		
960 - Temporary Sediment Trap	A small temporary ponding basin formed by construction of an embankment or excavated basin.	Slight increase because of increased infiltration.	Slight to moderate increase because of increased infiltration.	Slight increase because of increased infiltration.		Moderate to significant decrease because of trapped sediment and debris, depending on storage available, and area controlled.	Moderate to significant decrease because of trapped sediment and debris, depending on storage available, and area controlled.	Moderate to significant decrease because of trapped sediment and debris, depending on storage available, and area controlled.		
965 - Temporary Seeding	Planting rapid-growing annual grasses or small grains to provide initial, temporary coverage for erosion control on disturbed areas.	Slight to moderate increase because of increased infiltration depending on species of selected to site location.	Slight to moderate decrease because of increased infiltration.	Negligible.		Significant decrease because of vegetative cover, reduced runoff, and sedimentation.	Moderate to significant decrease because of vegetative cover, reduced runoff, and sedimentation.	Slight to significant decrease because of reduced erosion and sediment.		
970 - Temporary Slope Drain	A flexible tubing or rigid conduit extending temporarily from the top to the bottom of a cut or fill slope.	Slight to significant temporary decrease due to water being collected and conveyed to an outlet.	Significant temporary decrease due to water being collected and conveyed to an outlet.	Negligible.		Negligible.	Negligible.	Negligible.		
975 - Temporary Stream Crossing	A bridge, ford, or temporary structure installed across a stream or watercourse for short-term use by construction vehicles or heavy equipment.	Not applicable.	Not applicable.	Not applicable.		Slight increase due to altered stream flow at crossing location.	Slight increase due to altered stream flow at crossing location.	Slight increase due to altered stream flow at crossing location.

ASPECTS/ PROBLEMS	PRACTICE	GROUND WATER CONTAMINANTS			SURFACE WATER CONTAMINANTS					
		PESTICIDES	NUTRIENTS AND ORGANICS	HEAVY METALS	PESTICIDES	NUTRIENTS AND ORGANICS	SUSPENDED SEDIMENT AND TURBIDITY	SALINITY	HEAVY METALS	PATHOGENS
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Water pollution problems from pesticides. Pesticide means "all" chemicals used to manage weeds, insects, and diseases.	Water pollution problems from natural or human-induced common nutrients of N, P, K, Ca, Na, and Mg.	Water pollution problems from natural and human-induced common metals or metal compounds, such as iron, lead, zinc, copper, and cobalt.	Surface water pollution problems from pesticides. Pesticide means "all" chemicals used to manage weeds, insects, and diseases.	Surface water pollution problems that result from the use of all applied plant nutrients with emphasis on phosphorus and total organic carbon.	Water pollution suspended sediment and turbidity. Suspended sediment is sediment held in surrounding fluid. Turbidity is reduced clarity of fluids because of presence of suspended matter.	Water pollution from common salts such as sodium, calcium, boron and selenium.	Water pollution from natural and human-induced common metals and metal compounds, such as iron, lead, zinc, copper, and cobalt.	Water pollution from bacteria, viruses, protozoans, helminths, and fungi. Pathogens can be transported in both fluid and particulate forms.
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
955 - Temporary Diversion	A temporary ridge or excavated channel or combination ridge and channel constructed across sloping land on a predetermined grade.	Slight increase because of increased infiltration of soluble pesticides.	Slight increase because of increased infiltration of solubles, such as nitrate nitrogen.	Negligible.	Slight decrease because of decrease in sediment bound pesticides.	Slight to moderate decrease because of decrease in sediment bound phosphorus and total organic carbon. Slight increase in off-site solubles because of increased concentrated flow.	Slight decrease because of reduced sediment yield.	Negligible.	Negligible to moderate decrease because of managed runoff. Could be significant decrease if diversion is placed above a contaminant waste source with metals.	Negligible to moderate decrease because of managed runoff. Could be significant decrease if diversion is placed above a contaminant waste source with pathogens.
960 - Temporary Sediment Trap	A small temporary ponding basin formed by construction of an embankment or excavated basin.	Negligible to slight increase because of increased infiltration in the basin.	Negligible to slight increase because of increased infiltration in the basin.	Negligible.	Slight decrease of water soluble pesticides because of retention and slight to significant decrease in soil attached pesticides trapped in a basin.	Slight decrease of water soluble nutrients because of retention. Slight to significant decrease in soil attached nutrients and organics trapped in the basin, depending on particle size, available storage, and area controlled.	Moderate to significant decrease in sediment because of trapping and slight to significant decrease in turbidity because of retention and ponding.	Slight decrease for soil attached materials trapped and negligible for water soluble materials.	Moderate to significant decrease for heavy metals attached to soil particles.	Negligible to slight decrease because of attached material trapped with the sediment.
965 - Temporary Seeding	Planting rapid-growing annual grasses or small grains to provide initial, temporary coverage for erosion control on disturbed areas.	Negligible.	Negligible.	Negligible.	Negligible.	Negligible.	Moderate to significant decrease because of decreased sediment delivery.	Slight decrease because of reduced erosion and runoff.	Slight to moderate decrease because of reduced erosion and sediment yield.	Negligible.
970 - Temporary Slope Drain	A flexible tubing or rigid conduit extending temporarily from the top to the bottom of a cut or fill slope.	Slight to moderate decrease due to runoff being collected and conveyed to an outlet.	Slight to moderate decrease due to runoff being collected and conveyed to an outlet.	Negligible.	Slight to moderate increase due to runoff being collected and conveyed to an outlet.	Slight to moderate increase due to runoff being collected and conveyed to an outlet.	Negligible.	Slight to moderate increase due to runoff being collected and conveyed to an outlet.	Slight increase due to runoff being collected and conveyed to an outlet.	Negligible.
975 - Temporary Stream Crossing	A bridge, ford, or temporary structure installed across a stream or watercourse for short-term use by construction vehicles or heavy equipment.	Not Applicable.	Not Applicable.	Not Applicable.	Negligible.	Negligible.	Slight increase due to equipment entering stream where fords are used.	Negligible.	Negligible.	Negligible.

CONSIDERATIONS:		(1) QUANTITY								
ASPECTS/ PROBLEMS	PRACTICE	EXCESS AMOUNTS				RESTRICTED CAPACITY FROM SEDIMENT DEPOSITION IN SMALL CONVEYANCE		RESTRICTED CAPACITY FOR SEDIMENT DEPOSITION		
		SEEPS	RUNOFF/FLOODING	EXCESS SUBSURFACE WATER		ON-SITE	OFF-SITE	WATER BODIES, STREAMS, LAKES		
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Subsurface water flows onto the surface of the land.	Water accumulates on the surface of the land.	Subsurface water accumulates in the soil profile, which adversely affects plant growth and production operations.		Water quantity that affects drainage ditches, road ditches, culverts, and canals.	Water quantity that affects drainage ditches, road ditches, culverts, and canals.	Water quantity that is affected because of the loss of storage capacity as well as the loss of conveyance capacity.		
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
980 - Temporary Swale	A temporary excavated drainageway.	Negligible.	Moderate to significant decrease because of providing stable outlet.	Negligible.		Slight to moderate decrease because of decreased sediment loads by treating the eroding drainage way.	Moderate to significant decrease because of decreased sediment loads.	Slight to moderate decrease because of decreased sediment loads.		
981 - Topsoiling	Methods of preserving and using topsoil to enhance final site stabilization with vegetation.	Slight to moderate increase because of increased infiltration.	Slight to moderate decrease because of increased infiltration.	Slight to moderate increase because of increased infiltration.		Slight to moderate decrease because of decreased sediment yield, water management, and stabilization.	Slight to moderate decrease because of decreased sediment yield, water management, and stabilization.	Slight to moderate decrease because of decreased sediment yield, water management, and stabilization.		
984 - Tree and Forest Ecosystem Preservation	The preservation of contiguous stands of trees from damage during construction operations.	Not determined yet.	Not determined yet.	Not determined yet.		Not determined yet.	Not determined yet.	Not determined yet.		
985 - Tree and Shrub Planting	Planting of selected trees and shrubs.	Moderate to significant decrease depending upon species and proximity to seep due to increased plant uptake and transpiration.	Slight to moderate decrease because of improved land cover and retardance of runoff.	Moderate to significant decrease dependent on species used because of increased plant uptake and transpiration.		Slight to moderate decrease because of increased protective vegetation and reduced runoff.	Slight to moderate decrease because of increased protective vegetation and reduced runoff.	Slight to moderate decrease because of increased protective vegetation and reduced runoff.		
990 - Tree Protection	The protection of individual trees from damage during construction operations.	Moderate to significant decrease depending upon species and proximity to seep due to increased plant uptake and transpiration.	Slight to moderate decrease because of maintaining land cover.	Slight to moderate decrease dependent on species used because of increased plant uptake and transpiration.		Slight increase because of increased protective vegetation and reduced runoff.	Slight to moderate decrease because of increased protective vegetation and reduced runoff.	Slight to moderate decrease because of increased protective vegetation and reduced runoff.

Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.
995 - Vegetative Streambank Stabilization	The stabilization and protection of eroding streambanks with selected vegetation.	Not Applicable.	Not Applicable.	Not Applicable.	Negligible.	Slight decrease because of decreased erosion of streambank soil profiles.	Slight to significant decrease especially for fine textured streambanks because of decreased erosion and sediment delivered.	Slight decrease for saline soils because of decreased erosion and sediment delivery.	Negligible.	Negligible.
996 - Well Decommissioning	The sealing and permanent closure of a water well, boring, or monitoring well.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.

CONSIDERATIONS:		(1) QUANTITY		(2) CONDITION						
ASPECTS/ PROBLEMS		AIRBORNE ODORS	FUNGI, MOLDS, POLLEN	AIR TEMPERATURE	AIR MOVEMENT	HUMIDITY				
PRACTICE										
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Objectionable odors from such sources as waste, storage areas, waste lagoons, and other organics.	Production and release of fungi, molds, and pollen by components of a practice.	Improper temperature for development of flora and fauna. Zone of influence from ground level to 10 times plant height.	Improper air movement for flora and fauna. Zone of influence from ground level to 10 times plant height.	Improper level of humidity for flora and fauna health.				
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
800 - Urban Stormwater Wetlands	A constructed system of shallow pools that create growing conditions for wetland plants to lessen the impacts of stormwater quality and quantity in urban areas.	Negligible to significant decrease because of increased vegetative cover. Slight to moderate increase because some wetland odors are objectionable to some people.	Slight increase because of greater variety of plants.	Slight to moderate decrease in summer because of increased evaporation and transpiration.	Slight to moderate decrease because of increased hydrophytic vegetation.	Moderate increase because of increased evaporation and transpiration.				
806 - Construction Road Stabilization	The stabilization of temporary construction access routes, subdivision roads, on-site vehicle transportation roads, and construction parking areas with stone immediately after grading.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.				
808 - Culvert Inlet Protection	A temporary sediment filter located at the inlet to storm sewer culverts.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.				
815 - Diversion	A channel and supporting ridge constructed across the slope to collect and divert runoff.	Not applicable.	Not applicable.	Not applicable.	Negligible.	Not applicable.				
820 - Diversion Dike	A dike or dike and channel constructed along the perimeter of a disturbed construction area.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.				

CONSIDERATIONS:		(1) QUANTITY		(2) CONDITION						
ASPECTS/ PROBLEMS		AIRBORNE ODORS	FUNGI, MOLDS, POLLEN	AIR TEMPERATURE	AIR MOVEMENT	HUMIDITY				
PRACTICE										
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Objectionable odors from such sources as waste, storage areas, waste lagoons, and other organics.	Production and release of fungi, molds, and pollen by components of a practice.	Improper temperature for development of flora and fauna. Zone of influence from ground level to 10 times plant height.	Improper air movement for flora and fauna. Zone of influence from ground level to 10 times plant height.	Improper level of humidity for flora and fauna health.				
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
825 - Dust Control	Controlling dust blowing and movement on construction sites and roads.	Negligible to significant increase depending on the type, extent and frequency of materials applied.	Not applicable.	Not applicable.	Negligible.	Negligible.				
830 - Erosion Blanket	The application of a preformed protective blanket of straw or other plant residue, or plastic fibers formed into a mat, usually with a plastic mesh on one or both sides.	Not applicable.	Not applicable.	Not applicable.	Negligible.	Negligible.				
835 - Filter Strip	A created or preserved area of vegetation designed to remove sediment and other pollutants and to enhance the infiltration of surface water runoff.	Not applicable.	Slight to significant increase in problem depending on species present.	Slight decrease because of the effects of vegetative cover.	Slight decrease because of the effects of vegetative cover.	Slight decrease because of the effects of vegetative cover.				
840 - Grass-Lined Channel	A natural or constructed channel that is shaped or graded to required dimensions and established with suitable vegetation for stable conveyance of runoff.	Not applicable.	Slight increase because of permitting plants to mature.	Not applicable.	Negligible.	Negligible.				
841 - Impoundment Structure-Full Flow	A dam or excavation which creates an impoundment to collect and store debris, sediment, or water.	Negligible.	Negligible.	Not applicable.	Not applicable.	Not applicable.				

CONSIDERATIONS:		(1) QUANTITY		(2) CONDITION

Improper air movement for flora and fauna. Zone of influence from ground level to 10 times plant height.	Improper level of humidity for flora and fauna health.				
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
905 - Rock Check Dam	A small rock dam constructed across a grassed swale or road ditch.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.				
910 - Rock Outlet Protection	A section of rock protection placed at the outlet end of culverts, conduits, or channels.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.				
920 - Silt Fence	A temporary barrier of entrenched geotextile fabric stretched across and attached to supporting posts used to intercept sediment-laden runoff from small drainage areas of disturbed soil.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.				
925 - Sodding	Stabilization of fine graded disturbed areas by laying a continuous cover of grass sod.	Not applicable.	Negligible.	Slight decrease because of vegetative cover effects on temperature extremes.	Negligible.	Moderate increase at ground level. Slight increase above plants.				
930 - Stabilized Construction Entrance	A stabilized pad of aggregate underlain with filter fabric at any point where traffic enters or leaves a construction site to or from a public right-of-way, street, alley or parking area.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.				

CONSIDERATIONS:		(1) QUANTITY		(2) CONDITION

PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
980 - Temporary Swale	A temporary excavated drainageway.	Negligible.	Slight increase due to permitting plants to mature.	Not applicable.	Negligible.	Not applicable.				
981 - Topsoiling	Methods of preserving and using topsoil to enhance final site stabilization with vegetation.	Negligible.	Slight to significant decrease because of surface cover.	Negligible.	Negligible.	Negligible.				
984 - Tree and Forest Ecosystem Preservation	The preservation of contiguous stands of trees from damage during construction operations.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.				
985 - Tree and Shrub Planting	Planting of selected trees and shrubs.	Negligible.	Slight increase because of land use.	Slight to moderate decrease because of absorption of solar radiation and increased transpiration.	Moderate decrease because of increased vegetative cover and obstruction of surface wind patterns.	Slight to moderate increase because of increased transpiration.				
990 - Tree Protection	The protection of individual trees from damage during construction operations.	Negligible.	Slight increase because of land use.	Slight to moderate decrease because of absorption of solar radiation and increased transpiration.	Moderate decrease because of increased vegetative cover and obstruction of surface wind patterns.	Slight to moderate increase because of increased transpiration.				

CONSIDERATIONS:		(1) QUANTITY		(2) CONDITION						
ASPECTS/ PROBLEMS		AIRBORNE ODORS	FUNGI, MOLDS, POLLEN	AIR TEMPERATURE	AIR MOVEMENT	HUMIDITY				
PRACTICE										
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Objectionable odors from such sources as waste, storage areas, waste lagoons, and other organics.	Production and release of fungi, molds, and pollen by components of a practice.	Improper temperature for development of flora and fauna. Zone of influence from ground level to 10 times plant height.	Improper air movement for flora and fauna. Zone of influence from ground level to 10 times plant height.	Improper level of humidity for flora and fauna health.				
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
991 - Tree Protection - Augering	Underground construction such as utility work by augering (tunneling) through an individual tree's Critical Root Zone (CRZ).	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.				
995 - Vegetative Streambank Stabilization	The stabilization and protection of eroding streambanks with selected vegetation.	Not applicable.	Negligible.	Not applicable.	Not applicable.	Not applicable.				
996 - Well Decommissioning	The sealing and permanent closure of a water well, boring, or monitoring well.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.				

RESOURCE: PLANTS

Urban Conservation Practice Physical Effects

CONSIDERATIONS:		(1) QUANTITY		(2) CONDITION	(3) MANAGEMENT					
ASPECTS/ PROBLEMS		PLANTS ARE NOT WELL ADAPTED TO SITE	PLANTS ARE UNSUITABLE FOR INTENDED USE	HEALTH AND VIGOR	ESTABLISHMENT, GROWTH, AND HARVEST	NUTRIENT MANAGEMENT	PESTS (BRUSH, WEEDS, INSECTS, DISEASES, AND FUNGI)			
PRACTICE										
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Plants are not adapted to soil and climatic conditions of the area. (Select a better adapted species or modify site conditions.)	Plant of concern does not meet the needs and objectives of the manager, such as by providing quantity and quality of desired food or forage, controlling erosion, improved soil condition, conserving water, adding beauty, providing habitat for animals.	Plants do not manufacture sufficient plant food to continue the growth cycle or to reproduce.	The management scheme or plan does not provide the proper techniques and timing to meet the plant needs of establishment, growth, and harvest.	The correct amount of plant nutrients are not available to meet plant needs.	Pests are not managed to meet the needs of the plants of concern and the manager's objectives and resource management objectives.			
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
800 - Urban Stormwater Wetlands	A constructed system of shallow pools that create growing conditions for wetland plants to lessen the impacts of stormwater quality and quantity in urban areas.	Moderate to significant decrease because of establishment of adapted vegetation, creation of impoundments, and manipulation of water levels.	Moderate to significant decrease because of establishment of desired vegetation.	Moderate to significant decrease because of creation of impoundments and manipulation of water levels.	Moderate to significant decrease because of creation of impoundments and/or manipulation of water levels resulting in increased productivity of wetland plants.	Not applicable.	Moderate to significant decrease because permanent adapted vegetation will result in less pests and active management will control pests.			
806 - Construction Road Stabilization	The stabilization of temporary construction access routes, subdivision roads, on-site vehicle transportation roads, and construction parking areas with stone immediately after grading.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.			
808 - Culvert Inlet Protection	A temporary sediment filter located at the inlet to storm sewer culverts.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.			
815 - Diversion	A channel and supporting ridge constructed across the slope to collect and divert runoff.	Slight to significant decrease because of change in available moisture.	Not applicable.	Slight to moderate decrease because of reduced stress from excess water.	Significant decrease because of improvement in area protected by diversion.	Not applicable.	Slight increase because of improved pest habitat on vegetated diversions.			
820 - Diversion Dike	A dike or dike and channel constructed along the perimeter of a disturbed construction area.	Negligible to significant decrease because of site modification from flood water management.	Not applicable.	Slight to significant decrease because of improved soil, water, and plant relationship due to water management.	Slight to significant decrease because of improved soil, water, and plant relationship due to water management.	Not applicable.	Negligible.			

CONSIDERATIONS:		(1) QUANTITY		(2) CONDITION	(3) MANAGEMENT					
ASPECTS/ PROBLEMS		PLANTS ARE NOT WELL ADAPTED TO SITE	PLANTS ARE UNSUITABLE FOR INTENDED USE	HEALTH AND VIGOR	ESTABLISHMENT, GROWTH, AND HARVEST	NUTRIENT MANAGEMENT	PESTS (BRUSH, WEEDS, INSECTS, DISEASES, AND FUNGI)			
PRACTICE										
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Plants are not adapted to soil and climatic conditions of the area. (Select a better adapted species or modify site conditions.)	Plant of concern does not meet the needs and objectives of the manager, such as by providing quantity and quality of desired food or forage, controlling erosion, improved soil condition, conserving water, adding beauty, providing habitat for animals.	Plants do not manufacture sufficient plant food to continue the growth cycle or to reproduce.	The management scheme or plan does not provide the proper techniques and timing to meet the plant needs of establishment, growth, and harvest.	The correct amount of plant nutrients are not available to meet plant needs.	Pests are not managed to meet the needs of the plants of concern and the manager's objectives and resource management objectives.			
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
825 - Dust Control	Controlling dust blowing and movement on construction sites and roads.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.			
830 - Erosion Blanket	The application of a preformed protective blanket of straw or other plant residue, or plastic fibers formed into a mat, usually with a plastic mesh on one or both sides.	Not applicable.	Not applicable.	Slight decrease due to protection of young plants and moisture conservation provided by erosion blanket.	Slight decrease due to protection of young plants and moisture conservation provided by erosion blanket.	Negligible.	Moderate to significant decrease due to protection of young plants.			
835 - Filter Strip	A created or preserved area of vegetation designed to remove sediment and other pollutants and to enhance the infiltration of surface water runoff.	Significant decrease because of proper plant selection.	Significant decrease because of proper plant selection.	Slight decrease because of erosion control. Slight increase because of deposition within the filter strip.	Not applicable.	Not applicable.	Slight to moderate increase because of improved habitat for pests.			
840 - Grass-Lined Channel	A natural or constructed channel that is shaped or graded to required dimensions and established with suitable vegetation for stable conveyance of runoff.	Significant decrease because of proper plant selection and site modification.	Significant decrease because of proper plant selection.	Slight decrease because of erosion control. Slight increase because of deposition within the waterway.	Slight decrease because of improved farmability.	Not applicable.	Slight increase or decrease because of improved habitat for pests as well as beneficial organisms.			
841 - Impoundment Structure-Full Flow	A dam or excavation which creates an impoundment to collect and store debris, sediment, or water.	Not applicable.	Not applicable.	Moderate to significant decrease when used to facilitate grazing management.	Slight to significant decrease when used to facilitate grazing management.	Not applicable.	Negligible.

CONSIDERATIONS:		(1) QUANTITY		(2) CONDITION	(3) MANAGEMENT					
ASPECTS/ PROBLEMS		PLANTS ARE NOT WELL ADAPTED TO SITE	PLANTS ARE UNSUITABLE FOR INTENDED USE	HEALTH AND VIGOR	ESTABLISHMENT, GROWTH, AND HARVEST	NUTRIENT MANAGEMENT	PESTS (BRUSH, WEEDS, INSECTS, DISEASES, AND FUNGI)			
PRACTICE										
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Plants are not adapted to soil and climatic conditions of the area. (Select a better adapted species or modify site conditions.)	Plant of concern does not meet the needs and objectives of the manager, such as by providing quantity and quality of desired food or forage, controlling erosion, improved soil condition, conserving water, adding beauty, providing habitat for animals.	Plants do not manufacture sufficient plant food to continue the growth cycle or to reproduce.	The management scheme or plan does not provide the proper techniques and timing to meet the plant needs of establishment, growth, and harvest.	The correct amount of plant nutrients are not available to meet plant needs.	Pests are not managed to meet the needs of the plants of concern and the manager's objectives and resource management objectives.			
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
842 - Impoundment Structure-Routed	A dam or excavation which creates an impoundment to collect and store debris, sediment, or water.	Not applicable.	Not applicable.	Moderate to significant decrease when used to facilitate grazing management.	Slight to significant decrease when used to facilitate grazing management.	Not applicable.	Negligible.			
847 - Infiltration Trench	An excavated trench filled with coarse granular material in which stormwater runoff is collected for temporary storage and infiltration.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.			
850 - Inlet Protection - Block and Gravel	A sediment control barrier formed around a storm drain inlet by the use of standard concrete blocks and gravel.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.			
855 - Inlet Protection - Excavated Drain	An excavated area in the approach to a storm drain drop inlet or curb inlet.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.			
860 - Inlet Protection - Fabric Drop	A temporary fabric barrier placed around a drop inlet.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.			

CONSIDERATIONS:		(1) QUANTITY		(2) CONDITION	(3) MANAGEMENT					
ASPECTS/ PROBLEMS		PLANTS ARE NOT WELL ADAPTED TO SITE	PLANTS ARE UNSUITABLE FOR INTENDED USE	HEALTH AND VIGOR	ESTABLISHMENT, GROWTH, AND HARVEST	NUTRIENT MANAGEMENT	PESTS (BRUSH, WEEDS, INSECTS, DISEASES, AND FUNGI)			
PRACTICE										
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Plants are not adapted to soil and climatic conditions of the area. (Select a better adapted species or modify site conditions.)	Plant of concern does not meet the needs and objectives of the manager, such as by providing quantity and quality of desired food or forage, controlling erosion, improved soil condition, conserving water, adding beauty, providing habitat for animals.	Plants do not manufacture sufficient plant food to continue the growth cycle or to reproduce.	The management scheme or plan does not provide the proper techniques and timing to meet the plant needs of establishment, growth, and harvest.	The correct amount of plant nutrients are not available to meet plant needs.	Pests are not managed to meet the needs of the plants of concern and the manager's objectives and resource management objectives.			
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
861 - Inlet Protection - Gravel & Wire Mesh	A temporary sediment control barrier formed around a storm drain inlet by the use of gravel and wire mesh.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.			
862 - Inlet Protection -Sod Filter	A sediment filter formed around a storm drain drop inlet by the use of sod.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.			
863 - Inlet Protection - Straw Bale Barrier	A temporary sediment control barrier formed around a storm drain drop inlet consisting of a row of entrenched and anchored straw bales.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.			
865 - Land Grading	Reshaping the ground surface to planned grades as determined by engineering survey evaluation and layout.	Slight to significant decrease because of improved water, soil, and air relationship.	Slight to significant decrease because of improved water, soil, and air relationship.	Slight to significant decrease because of improved water, soil, and air relationship.	Significant decrease because of improved water management.	Slight decrease because of improved soil, water, and air relationship.	Slight decrease because of uniformity of management.			
870 - Level Spreader	A device used to disperse concentrated runoff over the ground surface as sheet flow.	Slight to significant decrease due to change in soil moisture conditions.	Not applicable.	Slight decrease due to reduced plant damage and stress from uniformly dispersed water.	Negligible.	Not applicable.	Not applicable.			

CONSIDERATIONS:		(1) QUANTITY		(2) CONDITION	(3) MANAGEMENT					
ASPECTS/ PROBLEMS		PLANTS ARE NOT WELL ADAPTED TO SITE	PLANTS ARE UNSUITABLE FOR INTENDED USE	HEALTH AND VIGOR	ESTABLISHMENT, GROWTH, AND HARVEST	NUTRIENT MANAGEMENT	PESTS (BRUSH, WEEDS, INSECTS, DISEASES, AND FUNGI)			
PRACTICE										
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Plants are not adapted to soil and climatic conditions of the area. (Select a better adapted species or modify site conditions.)	Plant of concern does not meet the needs and objectives of the manager, such as by providing quantity and quality of desired food or forage, controlling erosion, improved soil condition, conserving water, adding beauty, providing habitat for animals.	Plants do not manufacture sufficient plant food to continue the growth cycle or to reproduce.	The management scheme or plan does not provide the proper techniques and timing to meet the plant needs of establishment, growth, and harvest.	The correct amount of plant nutrients are not available to meet plant needs.	Pests are not managed to meet the needs of the plants of concern and the manager's objectives and resource management objectives.			
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
875 - Mulching	The application of plant residues and other suitable materials to the soil surface.	Slight to moderate because of improved site conditions.	Not applicable.	Slight to moderate because of improved site conditions.	Slight to moderate because of improved site conditions.	Slight to moderate decrease because of increased infiltration and water use.	Negligible to slight decrease because of return of weed competition. Negligible to slight increase because of improved habitat for other pests.			
880 - Permanent Vegetation	Establishing permanent vegetative cover to stabilize disturbed or exposed areas.	Significant decrease because of proper plant selection and nutrient modification of site.	Significant decrease because of proper plant selection.	Significant decrease because of improved vegetation management and plant selection.	Significant decrease because of proper selection of plants and management.	Moderate to significant decrease because of properly managed plant needs.	Not applicable.			
890 - Permeable Pavement	A pavement consisting of materials having regularly interspersed void areas filled with pervious materials, such as vegetated soil, gravel or sand.	Slight decrease due to proper plant selection where void areas are filled with sod.	Slight decrease due to proper plant selection where void areas are filled with sod.	Slight decrease due to proper plant selection where void areas are filled with sod.	Slight decrease due to proper plant selection where void areas are filled with sod.	Moderate to significant decrease because of properly managed plant needs.	Not applicable.			
895 - Portable Sediment Tank	A compartmented container through which sediment-laden water is pumped to trap and retain the sediment.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.			
900 - Right-of-Way Diversion	A ridge or ridge and channel constructed diagonally across a sloping road or utility right-of-way that is subject to erosion.	Slight to significant decrease because of change in available moisture.	Not applicable.	Slight to moderate decrease because of reduced stress from excess water.	Significant decrease because of improvement in area protected by diversion.	Not applicable.	Slight increase because of improved pest habitat on vegetated diversions.

ASPECTS/ PROBLEMS		PLANTS ARE NOT WELL ADAPTED TO SITE	PLANTS ARE UNSUITABLE FOR INTENDED USE	HEALTH AND VIGOR	ESTABLISHMENT, GROWTH, AND HARVEST	NUTRIENT MANAGEMENT	PESTS (BRUSH, WEEDS, INSECTS, DISEASES, AND FUNGI)			
PRACTICE										
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Plants are not adapted to soil and climatic conditions of the area. (Select a better adapted species or modify site conditions.)	Plant of concern does not meet the needs and objectives of the manager, such as by providing quantity and quality of desired food or forage, controlling erosion, improved soil condition, conserving water, adding beauty, providing habitat for animals.	Plants do not manufacture sufficient plant food to continue the growth cycle or to reproduce.	The management scheme or plan does not provide the proper techniques and timing to meet the plant needs of establishment, growth, and harvest.	The correct amount of plant nutrients are not available to meet plant needs.	Pests are not managed to meet the needs of the plants of concern and the manager's objectives and resource management objectives.			
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
905 - Rock Check Dam	A small rock dam constructed across a grassed swale or road ditch.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.			
910 - Rock Outlet Protection	A section of rock protection placed at the outlet end of culverts, conduits, or channels.	Moderate to significant decrease because of site modification by structure and stabilization for vegetative establishment and growth.	Not applicable.	Negligible.	Moderate to significant decrease because of site modification by structure and stabilization for vegetative establishment and growth.	Not applicable.	Not applicable.			
920 - Silt Fence	A temporary barrier of entrenched geotextile fabric stretched across and attached to supporting posts used to intercept sediment-laden runoff from small drainage areas of disturbed soil.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.			
925 - Sodding	Stabilization of fine graded disturbed areas by laying a continuous cover of grass sod.	Significant decrease because of proper plant selection and nutrient modification of site.	Significant decrease because of proper plant selection.	Significant decrease because of improved vegetative management and plant selection.	Significant decrease because of proper selection of plants and management.	Moderate to significant decrease because of properly managed plant needs.	Not applicable.			
930 - Stabilized Construction Entrance	A stabilized pad of aggregate underlain with filter fabric at any point where traffic enters or leaves a construction site to or from a public right-of-way, street, alley or parking area.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.

PRACTICE										
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Plants are not adapted to soil and climatic conditions of the area. (Select a better adapted species or modify site conditions.)	Plant of concern does not meet the needs and objectives of the manager, such as by providing quantity and quality of desired food or forage, controlling erosion, improved soil condition, conserving water, adding beauty, providing habitat for animals.	Plants do not manufacture sufficient plant food to continue the growth cycle or to reproduce.	The management scheme or plan does not provide the proper techniques and timing to meet the plant needs of establishment, growth, and harvest.	The correct amount of plant nutrients are not available to meet plant needs.	Pests are not managed to meet the needs of the plants of concern and the manager's objectives and resource management objectives.			
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
935 - Straw Bale Barrier	A temporary barrier of entrenched and anchored straw bales used to intercept sediment-laden runoff from small drainage areas of disturbed soil.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.			
940 - Structural Streambank Stabilization	Stabilization of eroding streambanks by use of designed structural measures.	Slight to moderate decrease due to stabilized bank creating suitable site conditions for plant growth where vegetative plantings are included with structural measures.	Slight to moderate decrease due to stabilized bank creating suitable site conditions for plant growth where vegetative plantings are included with structural measures.	Slight to moderate decrease due to stabilized bank creating suitable site conditions for plant growth where vegetative plantings are included with structural measures.	Slight to moderate decrease due to stabilized bank creating suitable site conditions for plant growth where vegetative plantings are included with structural measures.	Not applicable.	Not applicable.			
945 - Subsurface Drain	A conduit, such as corrugated plastic tubing, tile, or pipe, installed beneath the ground surface to collect and/or convey drainage water.	Slight to significant increase for non-hydrophytic plants and significant decrease for hydrophytic plants because subsurface water is removed from the soil profile.	Not applicable.	Slight to significant increase for non-hydrophytic plants and significant decrease for hydrophytic plants because subsurface water is removed from the soil profile.	Slight to significant decrease because subsurface water is removed from the soil profile.	Not applicable.	Slight to moderate decrease in aquatic pests and significant increase in terrestrial pests because subsurface water is removed from the soil profile.			
950 - Sump Pit	A temporary pit constructed to trap and filter water for pumping into a suitable discharge area.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.			
953 - Surface Roughening	A rough soil surface with horizontal grooves running across the slope on the contour, stair stepping, or tracking with construction equipment.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.			

RESOURCE: PLANTS

Urban Conservation Practice Physical Effects

ASPECTS/ PROBLEMS		PLANTS ARE NOT WELL ADAPTED TO SITE	PLANTS ARE UNSUITABLE FOR INTENDED USE	HEALTH AND VIGOR	ESTABLISHMENT, GROWTH, AND HARVEST	NUTRIENT MANAGEMENT	PESTS (BRUSH, WEEDS, INSECTS, DISEASES, AND FUNGI)			
PRACTICE										
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Plants are not adapted to soil and climatic conditions of the area. (Select a better adapted species or modify site conditions.)	Plant of concern does not meet the needs and objectives of the manager, such as by providing quantity and quality of desired food or forage, controlling erosion, improved soil condition, conserving water, adding beauty, providing habitat for animals.	Plants do not manufacture sufficient plant food to continue the growth cycle or to reproduce.	The management scheme or plan does not provide the proper techniques and timing to meet the plant needs of establishment, growth, and harvest.	The correct amount of plant nutrients are not available to meet plant needs.	Pests are not managed to meet the needs of the plants of concern and the manager's objectives and resource management objectives.			
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
955 - Temporary Diversion	A temporary ridge or excavated channel or combination ridge and channel constructed across sloping land on a predetermined grade.	Slight to significant decrease because of change in available moisture.	Not applicable.	Slight to moderate decrease because of reduced stress from excess water.	Significant decrease because of improvement in area protected by diversion.	Not applicable.	Slight increase because of improved pest habitat on vegetated diversions.			
960 - Temporary Sediment Trap	A small temporary ponding basin formed by construction of an embankment or excavated basin.	Not applicable.	Not applicable.	Negligible to slight decrease below basin when trapped sediment is kept off field.	Negligible to slight decrease below basin when trapped sediment is kept off field.	Negligible.	Negligible to slight increase or decrease because of trapped seeds and/or weeds growing on the basin.			
965 - Temporary Seeding	Planting rapid-growing annual grasses or small grains to provide initial, temporary coverage for erosion control on disturbed areas.	Significant decrease because of proper plant selection and nutrient modification of site.	Significant decrease because of proper plant selection.	Significant decrease because of improved vegetative management and plant selection.	Significant decrease because of proper selection of plants and management.	Moderate to significant decrease because of properly managed plant needs.	Not applicable.			
970 - Temporary Slope Drain	A flexible tubing or rigid conduit extending temporarily from the top to the bottom of a cut or fill slope.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.			
975 - Temporary Stream Crossing	A bridge, ford, or temporary structure installed across a stream or watercourse for short-term use by construction vehicles or heavy equipment.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.			

CONSIDERATIONS:		(1) QUANTITY		(2) CONDITION	(3) MANAGEMENT

PRACTICE										
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Plants are not adapted to soil and climatic conditions of the area. (Select a better adapted species or modify site conditions.)	Plant of concern does not meet the needs and objectives of the manager, such as by providing quantity and quality of desired food or forage, controlling erosion, improved soil condition, conserving water, adding beauty, providing habitat for animals.	Plants do not manufacture sufficient plant food to continue the growth cycle or to reproduce.	The management scheme or plan does not provide the proper techniques and timing to meet the plant needs of establishment, growth, and harvest.	The correct amount of plant nutrients are not available to meet plant needs.	Pests are not managed to meet the needs of the plants of concern and the manager's objectives and resource management objectives.			
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
980 - Temporary Swale	A temporary excavated drainage way.	Significant decrease because of proper plant selection and site modification.	Significant decrease because of proper plant selection.	Slight decrease because of erosion control. Slight increase because of deposition within the waterway.	Slight decrease because of improved farmability.	Not applicable.	Slight increase or decrease because of improved habitat for pests as well as beneficial organisms.			
981 - Topsoiling	Methods of preserving and using topsoil to enhance final site stabilization with vegetation.	Moderate to significant decrease because of selecting proper plants and soil modification.	Significant decrease because of selecting proper plants.	Significant decrease because of selecting proper plants and soil modification.	Moderate to significant decrease because of selecting proper plants and soil modification.	Slight to moderate decrease because of soil modification.	Negligible.			
984 - Tree and Forest Ecosystem Preservation	The preservation of contiguous stands of trees from damage during construction operations.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.			
985 - Tree and Shrub Planting	Planting of selected trees and shrubs.	Moderate to significant decrease because of proper species selection.	Moderate to significant decrease because of proper species selection.	Not applicable.	Moderate to significant decrease because of proper species selection and planting techniques.	Moderate to significant decrease because of application of needed plant nutrients.	Moderate to significant decrease because of control of pests for establishment of trees.			
990 - Tree Protection	The protection of individual trees from damage during construction operations.	Not applicable.	Not applicable.	Significant decrease due to reduced damage provided by protective measures.	Moderate to significant decrease due to reduced damage provided by protective measures.	Not applicable.	Negligible.			

CONSIDERATIONS:		(1) QUANTITY		(2) CONDITION	(3) MANAGEMENT					
ASPECTS/ PROBLEMS		PLANTS ARE NOT WELL ADAPTED TO SITE	PLANTS ARE UNSUITABLE FOR INTENDED USE	HEALTH AND VIGOR	ESTABLISHMENT, GROWTH, AND HARVEST	NUTRIENT MANAGEMENT	PESTS (BRUSH, WEEDS, INSECTS, DISEASES, AND FUNGI)			
PRACTICE										
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Plants are not adapted to soil and climatic conditions of the area. (Select a better adapted species or modify site conditions.)	Plant of concern does not meet the needs and objectives of the manager, such as by providing quantity and quality of desired food or forage, controlling erosion, improved soil condition, conserving water, adding beauty, providing habitat for animals.	Plants do not manufacture sufficient plant food to continue the growth cycle or to reproduce.	The management scheme or plan does not provide the proper techniques and timing to meet the plant needs of establishment, growth, and harvest.	The correct amount of plant nutrients are not available to meet plant needs.	Pests are not managed to meet the needs of the plants of concern and the manager's objectives and resource management objectives.			
PRACTICE CODE AND NAME	OTHER EXPLANATIONS									
991 - Tree Protection - Augering	Underground construction such as utility work by augering (tunneling) through an individual tree's Critical Root Zone (CRZ).	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.			
995 - Vegetative Streambank Stabilization	The stabilization and protection of eroding streambanks with selected vegetation.	Significant decrease because of selection of adapted species and site modification.	Slight to significant decrease because of potential to introduce new plant type and stabilizes streambank for existing plants.	Negligible to moderate decrease because of improved environment for plant growth.	Negligible.	Negligible.	Negligible.			
996 - Well Decommissioning	The sealing and permanent closure of a water well, boring, or monitoring well.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.			

RESOURCE: ANIMALS

Urban Conservation Practice Physical Effects

CONSIDERATIONS:		(1) HABITAT		(2) MANAGEMENT					
ASPECTS/ PROBLEMS		FOOD	COVER OR SHELTER	QUANTITY AND QUALITY OF DRINKING WATER	POPULATION/ RESOURCE BALANCE	ANIMAL HEALTH			
PRACTICE									
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Quantity and quality of food are not provided to meet the seasonal requirements of the species of concern.	Adequate wildlife cover for the species of concern is not provided.	Adequate quantities of water of required quality are not provided for the species of concern.	Numbers and kinds of wildlife are not in balance with feed, forage, space, and habitat requirements.	Proper attention is not given to the health of the animal of concern. This includes considerations such as diseases, parasites, and insects.			
PRACTICE CODE AND NAME	OTHER EXPLANATIONS								
800 - Urban Stormwater Wetlands	A constructed system of shallow pools that create growing conditions for wetland plants to lessen the impacts of stormwater quality and quantity in urban areas.	Significant decrease because of establishment of adapted hydrophytes or upland food plants and maintenance of water quality.	Significant decrease because of establishment of adapted hydrophytes and nesting cover.	Slight to significant decrease because of creation and maintenance of impoundments.	Slight to significant decrease because of increased plant diversity and increased supply of needed food.	Moderate to significant decrease because of habitat improvement for wildlife. Moderate to significant increase because of insects, parasites, and diseases for domestic wildlife.			
806 - Construction Road Stabilization	The stabilization of temporary construction access routes, subdivision roads, on-site vehicle transportation roads, and construction parking areas with stone immediately after grading.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.			
808 - Culvert Inlet Protection	A temporary sediment filter located at the inlet to storm sewer culverts.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.			
815 - Diversion	A channel and supporting ridge constructed across the slope to collect and divert runoff.	Slight decrease because grass provides food source for wildlife on vegetated diversions.	Slight decrease because grass on vegetated diversions provides diversity, cover, and travel lanes.	Significant decrease because of increase in quantity where diversion diverts water to storage facility.	Slight decrease because of improvement in habitat.	Negligible.			
820 - Diversion Dike	A dike or dike and channel constructed along the perimeter of a disturbed construction area.	Negligible to slight decrease or increase because of water management.	Slight to moderate decrease because of vegetation diversity on dike and water management.	Negligible.	Slight to moderate decrease because of vegetation diversity on dike and water management.	Negligible.			

CONSIDERATIONS:		(1) HABITAT		(2) MANAGEMENT					
ASPECTS/ PROBLEMS		FOOD	COVER OR SHELTER	QUANTITY AND QUALITY OF DRINKING WATER	POPULATION/ RESOURCE BALANCE	ANIMAL HEALTH			
PRACTICE									
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Quantity and quality of food are not provided to meet the seasonal requirements of the species of concern.	Adequate wildlife cover for the species of concern is not provided.	Adequate quantities of water of required quality are not provided for the species of concern.	Numbers and kinds of wildlife are not in balance with feed, forage, space, and habitat requirements.	Proper attention is not given to the health of the animal of concern. This includes considerations such as diseases, parasites, and insects.			
PRACTICE CODE AND NAME	OTHER EXPLANATIONS								
825 - Dust Control	Controlling dust blowing and movement on construction sites and roads.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.			
830 - Erosion Blanket	The application of a preformed protective blanket of straw or other plant residue, or plastic fibers formed into a mat, usually with a plastic mesh on one or both sides.	Negligible.	Negligible.	Not applicable.	Not applicable.	Not applicable.			
835 - Filter Strip	A created or preserved area of vegetation designed to remove sediment and other pollutants and to enhance the infiltration of surface water runoff.	Negligible to moderate decrease because of added plant diversity depending on size of area and species seeded.	Negligible to significant decrease because of improvements in cover depending on plant species, size, location and management.	Slight to significant decrease because of reduced sediment and other pollutants.	Negligible to slight decrease because of increased plant diversity and improved habitat quality.	Slight to moderate increase because of potential to add pollutants in food chain if forage from filter strips is consumed by wildlife.			
840 - Grass-Lined Channel	A natural or constructed channel that is shaped or graded to required dimensions and established with suitable vegetation for stable conveyance of runoff.	Negligible to significant decrease because of increase in food depending on size of area and species seeded.	Slight to significant decrease because of increase in vegetation depending on plant species, size, location and management.	Negligible to significant decrease because of reduction in runoff of sediment.	Slight to moderate decrease because of increase in forage availability and habitat quality.	Negligible.			
841 - Impoundment Structure-Full Flow	A dam or excavation which creates an impoundment to collect and store debris, sediment, or water.	Slight to significant decrease because of distribution of wildlife for grazing and foraging on uplands. Provides food for some fish and some wildlife.	Slight to significant decrease because of increase in cover in pond area. Slight to significant increase if pond and surrounding area create concentration of animals.	Moderate to significant decrease because of providing water during critical periods.	Slight to significant decrease because of increase in habitat and forage use.	Slight to significant decrease because of improved water source. Slight to significant increase because of parasite problems caused by animal concentration.			

CONSIDERATIONS:		(1) HABITAT		(2) MANAGEMENT					
ASPECTS/ PROBLEMS		FOOD	COVER OR SHELTER	QUANTITY AND QUALITY OF DRINKING WATER	POPULATION/ RESOURCE BALANCE	ANIMAL HEALTH			
PRACTICE									
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Quantity and quality of food are not provided to meet the seasonal requirements of the species of concern.	Adequate wildlife cover for the species of concern is not provided.	Adequate quantities of water of required quality are not provided for the species of concern.	Numbers and kinds of wildlife are not in balance with feed, forage, space, and habitat requirements.	Proper attention is not given to the health of the animal of concern. This includes considerations such as diseases, parasites, and insects.			
PRACTICE CODE AND NAME	OTHER EXPLANATIONS								
842 - Impoundment Structure-Routed	A dam or excavation which creates an impoundment to collect and store debris, sediment, or water.	Slight to significant decrease because of distribution of wildlife for grazing and foraging on uplands. Provides food for some fish and some wildlife.	Slight to significant decrease because of increase in cover in pond area. Slight to significant increase if pond and surrounding area create concentration of animals.	Moderate to significant decrease because of providing water during critical periods.	Slight to significant decrease because of increase in habitat and forage use.	Slight to significant decrease because of improved water source. Slight to significant increase because of parasite problems caused by animal concentration.			
847 - Infiltration Trench	An excavated trench filled with coarse granular material in which stormwater runoff is collected for temporary storage and infiltration.	Slight to moderate decrease if area adjacent to pit or trench is established to permanent cover of mast producing plant species.	Slight to moderate decrease if area adjacent to pit or trench is established to permanent cover of mast producing plant species.	Slight decrease due to temporary water storage.	Slight to moderate decrease if area adjacent to pit or trench is established to permanent cover of mast producing plant species.	Negligible.			
850 - Inlet Protection - Block and Gravel	A sediment control barrier formed around a storm drain inlet by the use of standard concrete blocks and gravel.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.			
855 - Inlet Protection - Excavated Drain	An excavated area in the approach to a storm drain drop inlet or curb inlet.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.			
860 - Inlet Protection - Fabric Drop	A temporary fabric barrier placed around a drop inlet.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.			

CONSIDERATIONS:		(1) HABITAT		(2) MANAGEMENT					
ASPECTS/ PROBLEMS		FOOD	COVER OR SHELTER	QUANTITY AND QUALITY OF DRINKING WATER	POPULATION/ RESOURCE BALANCE	ANIMAL HEALTH			
PRACTICE									
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Quantity and quality of food are not provided to meet the seasonal requirements of the species of concern.	Adequate wildlife cover for the species of concern is not provided.	Adequate quantities of water of required quality are not provided for the species of concern.	Numbers and kinds of wildlife are not in balance with feed, forage, space, and habitat requirements.	Proper attention is not given to the health of the animal of concern. This includes considerations such as diseases, parasites, and insects.			
PRACTICE CODE AND NAME	OTHER EXPLANATIONS								
861 - Inlet Protection - Gravel & Wire Mesh	A temporary sediment control barrier formed around a storm drain inlet by the use of gravel and wire mesh.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.			
862 - Inlet Protection -Sod Filter	A sediment filter formed around a storm drain drop inlet by the use of sod.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.			
863 - Inlet Protection - Straw Bale Barrier	A temporary sediment control barrier formed around a storm drain drop inlet consisting of a row of entrenched and anchored straw bales.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.			
865 - Land Grading	Reshaping the ground surface to planned grades as determined by engineering survey evaluation and layout.	Slight to significant increase because of changes in water regime and decreased diversity.	Slight to significant increase because of changes in water regime and decreased diversity.	Negligible to slight increase because of less water standing in field.	Slight to significant increase or decrease depending upon target species because of changes in water regime.	Negligible.			
870 - Level Spreader	A device used to disperse concentrated runoff over the ground surface as sheet flow.	Slight decrease if established to seed or forage producing plant species.	Slight to moderate decrease if established to plant species and managed to provide wildlife habitat.	Negligible.	Slight decrease if established to seed or forage producing plant species.	Negligible.			

RESOURCE: ANIMALS

Urban Conservation Practice Physical Effects

CONSIDERATIONS:		(1) HABITAT		(2) MANAGEMENT					
ASPECTS/ PROBLEMS		FOOD	COVER OR SHELTER	QUANTITY AND QUALITY OF DRINKING WATER	POPULATION/ RESOURCE BALANCE	ANIMAL HEALTH			
PRACTICE									
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Quantity and quality of food are not provided to meet the seasonal requirements of the species of concern.	Adequate wildlife cover for the species of concern is not provided.	Adequate quantities of water of required quality are not provided for the species of concern.	Numbers and kinds of wildlife are not in balance with feed, forage, space, and habitat requirements.	Proper attention is not given to the health of the animal of concern. This includes considerations such as diseases, parasites, and insects.			
PRACTICE CODE AND NAME	OTHER EXPLANATIONS								
875 - Mulching	The application of plant residues and other suitable materials to the soil surface.	Negligible.	Negligible.	Negligible to moderate decrease because of reduced sediment yield.	Not applicable.	Not applicable.			
880 - Permanent Vegetation	Establishing permanent vegetative cover to stabilize disturbed or exposed areas.	Slight to significant decrease because of revegetating depending on size of area and plant species selected.	Slight to moderate decrease because of increased vegetation.	Significant decrease because of reduced erosion and infiltration.	Slight to significant decrease because of increased habitat quality.	Slight decrease because of improved habitat and food supply.			
890 - Permeable Pavement	A pavement consisting of materials having regularly interspersed void areas filled with pervious materials, such as vegetated soil, gravel or sand.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.			
895 - Portable Sediment Tank	A compartmented container through which sediment-laden water is pumped to trap and retain the sediment.	Not applicable.	Not applicable.	Slight to moderate decrease due to sediment trapping and removal.	Not applicable.	Not applicable.			
900 - Right-of-Way Diversion	A ridge or ridge and channel constructed diagonally across a sloping road or utility right-of-way that is subject to erosion.	Slight decrease because grass provides food source for wildlife on vegetated diversions.	Slight decrease because grass on vegetated diversions provides diversity, cover, and travel lanes.	Significant decrease because of increase in quantity where diversion diverts water to storage facility.	Slight decrease because of improvement in habitat.	Negligible.			

CONSIDERATIONS:		(1) HABITAT		(2) MANAGEMENT					
ASPECTS/ PROBLEMS		FOOD	COVER OR SHELTER	QUANTITY AND QUALITY OF DRINKING WATER	POPULATION/ RESOURCE BALANCE	ANIMAL HEALTH			
PRACTICE									
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Quantity and quality of food are not provided to meet the seasonal requirements of the species of concern. Numbers and kinds of wildlife are not in balance with feed, forage, space, and habitat requirements.	Proper attention is not given to the health of the animal of concern. This includes considerations such as diseases, parasites, and insects.			
PRACTICE CODE AND NAME	OTHER EXPLANATIONS								
905 - Rock Check Dam	A small rock dam constructed across a grassed swale or road ditch.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.			
910 - Rock Outlet Protection	A section of rock protection placed at the outlet end of culverts, conduits, or channels.	Negligible to moderate decrease because of stabilization.	Slight decrease because grass on vegetated diversions provides diversity, cover, and travel lanes.	Negligible to moderate decrease because of reduced sediment yield from channel source.	Slight decrease because of improvement in habitat.	Negligible.			
920 - Silt Fence	A temporary barrier of entrenched geotextile fabric stretched across and attached to supporting posts used to intercept sediment-laden runoff from small drainage areas of disturbed soil.	Not applicable.	Negligible to moderate decrease because of stabilization.	Slight to moderate decrease due to sediment trapping and removal.	Negligible.	Not applicable.			
925 - Sodding	Stabilization of fine graded disturbed areas by laying a continuous cover of grass sod.	Slight to significant decrease because of revegetating depending on size of area and plant species selected.	Slight to moderate decrease because of increased vegetation.	Significant decrease because of reduced erosion and infiltration.	Slight to significant decrease because of increased habitat quality.	Slight decrease because of improved habitat and food supply.			
930 - Stabilized Construction Entrance	A stabilized pad of aggregate underlain with filter fabric at any point where traffic enters or leaves a construction site to or from a public right-of-way, street, alley or parking area.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.			

CONSIDERATIONS:		(1) HABITAT		(2) MANAGEMENT					
ASPECTS/ PROBLEMS		FOOD	COVER OR SHELTER	QUANTITY AND QUALITY OF DRINKING WATER	POPULATION/ RESOURCE BALANCE	ANIMAL HEALTH			
PRACTICE									
TYPE OF PRACTICE	RESOURCE PROBLEM/ CONSIDERATIONS DEFINITION	Quantity and quality of food are not provided to meet the seasonal requirements of the species of concern.	Adequate wildlife cover for the species of concern is not provided.	Adequate quantities of water of required quality are not provided for the species of concern.	Numbers and kinds of wildlife are not in balance with feed, forage, space, and habitat requirements.	Proper attention is not given to the health of the animal of concern. This includes considerations such as diseases, parasites, and insects.			
PRACTICE CODE AND NAME	OTHER EXPLANATIONS								
935 - Straw Bale Barrier	A temporary barrier of entrenched and anchored straw bales used to intercept sediment-laden runoff from small drainage areas of disturbed soil.	Not applicable.	Not applicable.	Slight to moderate decrease due to sediment trapping and removal.	Not applicable.	Not applicable.			
940 - Structural Streambank Stabilization	Stabilization of eroding streambanks by use of designed structural measures.	Slight to significant decrease in food depending on whether vegetation treatment is used and species planted.	Slight to significant increase especially for vegetative streambank treatment or potential for vegetative treatment into or over structural treatment (riprap).	Negligible.	Negligible.	Negligible.			
945 - Subsurface Drain	A conduit, such as corrugated plastic tubing, tile, or pipe, installed beneath the ground surface to collect and/or convey drainage water.	Negligible to significant increase or decrease depending upon target species.	Negligible to significant increase or decrease because of change in vegetation.	Slight to significant increase because of removal of water. Slight to moderate decrease because of improved collection of ground water for conveyance to storage facility.	Negligible to significant increase or decrease because of changes in plant communities.	Negligible to significant decrease because of impact on pest habitat.			
950 - Sump Pit	A temporary pit constructed to trap and filter water for pumping into a suitable discharge area.	Not applicable.	Not applicable.	Slight to moderate decrease due to sediment trapping and removal and temporary water storage.	Not applicable.	Not applicable.			
953 - Surface Roughening	A rough soil surface with horizontal grooves running across the slope on the contour, stair stepping, or tracking with construction equipment.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.

Adequate wildlife cover for the species of concern is not provided.	Adequate quantities of water of required quality are not provided for the species of concern.	Numbers and kinds of wildlife are not in balance with feed, forage, space, and habitat requirements.	Proper attention is not given to the health of the animal of concern. This includes considerations such as diseases, parasites, and insects.			
PRACTICE CODE AND NAME	OTHER EXPLANATIONS								
955 - Temporary Diversion	A temporary ridge or excavated channel or combination ridge and channel constructed across sloping land on a predetermined grade.	Slight decrease because grass provides food source for wildlife on vegetated diversions.	Slight decrease because grass on vegetated diversions provides diversity, cover, and travel lanes.	Significant decrease because of increase in quantity where diversion diverts water to storage facility.	Slight decrease because of improvement in habitat.	Negligible.			
960 - Temporary Sediment Trap	A small temporary ponding basin formed by construction of an embankment or excavated basin.	Slight to moderate decrease when embankment is seeded to permanent cover.	Slight to moderate decrease when embankment is seeded to permanent cover.	Slight decrease if basin holds water and water is suited for use.	Not applicable.	Negligible to moderate increase because of concentration of pollutants.			
965 - Temporary Seeding	Planting rapid-growing annual grasses or small grains to provide initial, temporary coverage for erosion control on disturbed areas.	Slight to significant decrease because revegetating depending on size of area and plant species selected.	Slight to moderate decrease because of increased vegetation.	Significant decrease because of reduced erosion and infiltration.	Slight to significant decrease because of increased habitat quality.	Slight decrease because of improved habitat and food supply.			
970 - Temporary Slope Drain	A flexible tubing or rigid conduit extending temporarily from the top to the bottom of a cut or fill slope.	Not applicable.	Not applicable.	Not applicable.	Not applicable.	Not applicable.			
975 - Temporary Stream Crossing	A bridge, ford, or temporary structure installed across a stream or watercourse for short-term use by construction vehicles or heavy equipment.	Not applicable.	Not applicable.	Slight decrease due to reduced sediment load delivery by vehicles and heavy equipment.	Not applicable.	Not applicable.			

CONSIDERATIONS:		(1) HABITAT		(2) MANAGEMENT					
ASPECTS/ PROBLEMS		FOOD	COVER OR SHELTER	QUANTITY AND QUALITY OF DRINKING WATER	POPULATION/ RESOURCE BALANCE	ANIMAL HEALTH			
PRACTICE

Numbers and kinds of wildlife are not in balance with feed, forage, space, and habitat requirements.	Proper attention is not given to the health of the animal of concern. This includes considerations such as diseases, parasites, and insects.			
PRACTICE CODE AND NAME	OTHER EXPLANATIONS								
980 - Temporary Swale	A temporary excavated drainage way.	Negligible to significant decrease because of increase in food depending on size of area and species seeded.	Slight to significant decrease because of increase in vegetation depending on plant species, size, location, and management.	Negligible to significant decrease because of reduction of runoff of sediment and agricultural chemicals.	Slight to moderate decrease because of increase in forage availability and habitat quality.	Negligible.			
981 - Topsoiling	Methods of preserving and using topsoil to enhance final site stabilization with vegetation.	Moderate to significant decrease because of increased vegetation.	Moderate to significant decrease because of increased vegetation.	Slight to significant decrease because of reduced sediment yield, water management, and stabilization.	Slight to significant decrease because of vegetative cover.	Slight to significant decrease because of vegetative cover.			
984 - Tree and Forest Ecosystem Preservation	The preservation of contiguous stands of trees from damage during construction operations.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.			
985 - Tree and Shrub Planting	Planting of selected trees and shrubs.	Moderate to significant increase or decrease because of changes in vegetative types dependent on tree species planted, spacing of plantings, and animal species of concern.	Moderate to significant increase or decrease because of changes in vegetation types depend on tree species planted and animal species of concern.	Slight to significant increase or decrease because of effect on watershed hydrology dependent on number and location of trees planted.	Moderate to significant increase or decrease because of changes in vegetative types, dependent on tree species planted, spacing of plantings, and animal species of concern.	Moderate to significant increase or decrease because of changes in vegetative types, dependent on tree species planted, spacing of plantings, and animal species of concern.			
990 - Tree Protection	The protection of individual trees from damage during construction operations.	Slight to moderate decrease depending on species protected.	Slight to moderate decrease depending on species protected.	Slight to moderate increase or decrease due to effect on watershed hydrology depending on number of trees protected.	Slight to significant increase or decrease depending on tree species protected and animal species of concern.	Negligible.

991 - Tree Protection - Augering	Underground construction such as utility work by augering (tunneling) through an individual tree's Critical Root Zone (CRZ).	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.			
995 - Vegetative Streambank Stabilization	The stabilization and protection of eroding streambanks with selected vegetation.	Slight to significant decrease in food depending on vegetation treatment used and species planted.	Slight to significant increase especially for vegetative streambank treatment.	Negligible.	Negligible.	Negligible.			
996 - Well Decommissioning	The sealing and permanent closure of a water well, boring, or monitoring well.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.	Not determined yet.			

SECTION 9 - REFERENCES

INTRODUCTION

This section contains selected references in the fields of stormwater management, floodplain management, soil erosion and sediment control, and wetland and stream protection. Several of the references were used in the preparation of previous editions of this manual. The references that were chosen to be included are representative of materials that could be reviewed if a unit of government, consultant, or private citizen was interested in learning more about these subjects, or wanted to develop guidance or a regulatory mechanism (e.g., ordinance) to address these issues.

As new conservation practice standards are added to the manual, specific references used to prepare the standards will be included within the standard itself.

This section was revised in October 2001.

SECTION 10 - GLOSSARY

There are many terms used today in erosion and sediment control, work in environmental quality, resource planning, and air and water quality programs that many people do not fully understand. This glossary contains some terms not used in this publication. An attempt has been made to assemble a list of terms used in the field of Natural Resource Conservation in addition to those found in this guide book to aid the users to have a better understanding of the subject. Many of the definitions were taken from Resource Conservation Glossary, 3rd edition, Soil Conservation Society of America, 1982.

Acid Soil - Soil with pH value of less than 7.0. The term generally is applied to the surface layers or root zone unless otherwise specified.

Acre-Foot - The volume of water that will cover one acre to a depth of one foot. One acre-foot contains 325,851 gallons.

Aerial Photograph - A photograph of the earth's surface taken from airborne equipment, sometimes called aerial photo or air photograph.

Aggradation - The process of building up a surface or channel by deposition; the opposite of degradation. The process is sometimes referred to as siltation.

Agricultural Land - Land in farms regularly used for agricultural production. The term includes all land devoted to crop or livestock enterprises, for example, the farmstead lands, drainage and irrigation ditches, water supply, cropland, and grazing land of every kind in farms.

Agronomic Practices - The soil and crop activities employed in the production of farm crops, such as selecting seed, seedbed preparation, fertilizing, liming, manuring, seeding, cultivation, harvesting, curing, crop sequence, crop rotations, cover crops, strip cropping, pasture development, etc.

Alluvial - Pertaining to material that is transported and deposited by running water.

Angle of Repose - The angle between the horizontal and the maximum slope that a soil assumes through natural processes.

Annual Flood - The highest peak discharge in a water year.

Anti-seep Collar - A device constructed around a pipe or other conduit placed through a dam, dike, or levee for the purpose of reducing seepage losses and piping failures.

Anti-vortex Device - A facility placed at the entrance to a pipe conduit structure such as a drop inlet spillway or hood inlet spillway to prevent air from entering the structure when the pipe is flowing full.

Apron - A floor or lining to protect a surface from erosion. For example, the pavement below chutes, spillways, or at the toes of dams.

Aquifer - A geologic formation or structure that transmits water in sufficient quantity to supply the needs for a water development. The term water-bearing is sometimes used synonymously with aquifer when a stratum furnishes water for a specific use. Aquifers are usually saturated sands, gravel, fractures, cavernous and vesicular rock.

Auxiliary Spillway - A dam spillway built to carry runoff in excess of that carried by the principal spillway.

Available Water-holding Capacity (soils) - The capacity to store water available for use by plants, usually expressed in linear depths of water per unit depth of soil. Commonly defined as the difference between the percentage of soil water at field capacity and the percentage at wilting point. This difference multiplied by the bulk density and divided by 100 gives a value in surface inches of water per inch depth of soil. See field capacity; wilting point.

Base Flow - The stream discharge from ground water runoff.

Bedding - The process of laying a drain or other conduit in its trench and tamping earth around the conduit to form its bed. The manner of bedding may be specified to conform to the earth load and conduit strength.

Bedload - The sediment that moves by sliding, rolling, or bounding on or very near the streambed; sediment moved mainly by tractive or gravitational forces or both but at velocities less than the surrounding flow.

Bedrock - The more or less solid rock in place either on or beneath the surface of the earth. It may be soft or hard and have a smooth or irregular surface.

Berm - A ledge or shelf that breaks the continuity of a slope, as a ledge across the face of a dam or the shoulder along a paved road.

Blind Drain - A type of drain consisting of an excavated trench refilled with previous materials, such as coarse sand, gravel or crushed stones, through whose voids water percolates and flows toward an outlet. Often referred to as a French drain because of its initial development and widespread use in France.

Borrow Area - A source of earth fill materials used in the construction of embankments or other earth fill structures.

Bottomlands - A term often used to define lowlands adjacent to streams (flood plains in rural areas).

Broadcast Seeding - Any method of planting seed that scatters the seed in a random pattern on the surface of the soil.

Cantilever Outlet - A discharge pipe extending beyond its support.

Cascades - Section of stream without pools consisting primarily of bedrock, rubble, gravel, or other such material. Current is usually more swift than in riffles.

Channel - A natural or artificial stream that conveys water. Channels are often further classified by their size and purpose. For example, there are primary and secondary channels based on size, but diversions, waterways, and chutes are also channels.

Channel Improvement - The improvement of the flow characteristics of a channel by clearing, excavating, realigning, lining, or other means in order to increase its capacity. The term is sometimes used to connote channel stabilization.

Channel Stabilization - Erosion prevention and stabilization of velocity distribution in a channel using jetties, drops, revetments, vegetation, and other measures.

Check Dam - Small dam constructed in a gully or other small water- course to decrease the streamflow velocity, minimize channel scour, and promote deposition of sediment.

Chiseling - 1. Performing tillage that breaks or loosens the soil without inverting it. 2. Tilling the soil with a chisel implement. The depth of chiseling is arbitrarily limited to 16 inches or less; beyond 16 inches, the tillage becomes subsoiling.

Chute - A high velocity, open channel for conveying water to a lower level without erosion.

Clay - 1. A soil textural class including particles less than 0.002 millimeters in diameter. 2. A fine-grained soil with a high plasticity index in relation to the liquid limits. 3. Soils with a high clay content which are difficult to excavate or till; sometimes called heavy soils.

Clearcutting (forestry) - A method of cutting that removes the entire timber stand on the area cut. Contrast with selective cutting.

Climate - The sum total of all atmospheric or meteorological influences, principally temperature, moisture, wind, pressure, and evaporation, which combine to characterize a region and give it individuality by influencing the nature of its land forms, soils, vegetation, and land use. Contrast with weather.

Climax Vegetation - Relatively stable vegetation in equilibrium with its environment and with good reproduction of the dominant plants.

Closed Drain - An underground pipe for intercepting and conveying water.

Compost - Organic residues, or a mixture of organic residues and soil, that have been piled and allowed to undergo biological decomposition.

Conduit - Any structure intended for the conveyance of water, whether open or closed.

Conservation - The protection, improvement, and wise use of natural resources according to nature's principles that will assure their highest environmental, economic and social benefits.

Conservation District - A public organization created under state enabling law or a special-purpose district to develop and carry out a program of soil, water, and related resource conservation, use, and development within its boundaries; usually a subdivision of state government with a local governing body and always with limited authorities. Often it is called a soil conservation district or a soil and water conservation district.

Contour - An imaginary line on the surface of the earth connecting points of the same elevation or a line drawn on a map connecting points of the same elevation. This term may include allowable deviations from the true contour.

Core Wall - A wall of masonry, sheet piling, or compacted earth placed near the center of a dam or embankment to reduce seepage.

Cradle - A device, usually concrete, used to support a pipe conduit.

Crest - 1. The top of a dam, dike, spillway or weir, frequently restricted to overflow portion. 2. The summit of a wave or peak of a flood.

Cubic Foot Per Second - The rate of fluid flow at which 1 cubic foot of fluid passes a measuring point in one second. Abbreviated as cfs. Syn. with second-foot and CUSEC.

Cut - 1. A portion of land surface or area from which earth has been removed or will be removed by excavation. 2. The depth below original ground surface to excavated surface.

Cut-and-Fill - The process of earth moving by excavating part of an area and using the excavated material for adjacent embankments or fill areas.

Cutoff - 1. A wall, collar, narrow excavation, or other structure, such as a trench, constructed along the centerline of a dam, dike, levee, or embankment, and filled with relatively impervious material intended to reduce seepage of water through porous strata. 2. In river hydraulics, the new and shorter channel formed either naturally or artificially when a stream cuts through the neck of a bend.

Dam - A barrier to confine, divert, or raise water for storage; to create a hydraulic head; to prevent gully erosion; or to retain sediment, rock, and other debris.

Debris - 1. A term applied to the loose material arising from the disintegration of rocks and vegetative material; transportable by streams, ice, or floods. 2. Stones, scrap material; stumps, limbs, and other undesirable vegetative material; waste and trash on a site.

Debris Basin - A basin constructed in a waterway or at other suitable locations to trap sediment and debris.

Degradation - To wear down through erosion, especially through stream action.

Demography - The statistical study of human vital statistics and population dynamics.

Design Highwater - The elevation of the water surface as determined by the flow conditions of the design floods.

Design Life - The period of time for which a facility is expected to perform its intended function.

Dike - An embankment constructed of earth or other suitable materials to protect land against overflow from streams, lakes, or tidal influences or to protect flat land areas from diffused surface water.

Discharge (hydraulics) - 1. Rate of flow, specifically fluid flow. 2. A volume of fluid passing a point per unit of time, commonly expressed as cubic feet per second, million gallons per day, gallons per minute, or cubic meters per second.

Diversion - A channel with a supporting ridge on the lower side constructed across a slope for the purpose of intercepting and diverting water.

Drain - 1. A buried pipe or other conduit (closed drain). 2. A ditch (open drain) for carrying off surplus surface water or ground water.

Drainage - 1. The removal of excess surface or ground water from land by means of surface or subsurface drains. 2. Soil characteristics that affect natural drainage.

Drainage Area - The land area from which water drains to a given point.

Drawdown - Lowering of the water surface (in open channel flow), water table, or piezometric surface (in groundwater flow) resulting from a withdrawal of water.

Drill (seeding) - A method of planting seed with an implement that places the seed in closely spaced rows on or slightly below the surface of the soil

Drop Inlet Spillway - An overfall structure in which the water drops through a vertical riser connected to a discharge conduit.

Drop Spillway - An overfall structure in which the water drops over a vertical wall onto an apron at a lower elevation.

Drop Structure - A structure for dropping water to a lower level and dissipating its surplus energy.

Dry Well - A pit or hole in the ground walled up with unmortared stone, concrete blocks, etc. so as to permit drainage into the ground. Normally dry.

Ecosystem - Energy-driven complex of a community of organisms and its controlling environment.

Effluent - 1. The discharge or outflow of water from ground or subsurface storage. 2. The fluids discharged from domestic, industrial, and municipal waste collection systems or treatment facilities.

Embankment - A man-made deposit of soil, rock, or other materials used to form an impoundment.

Emergency Spillway - A spillway used to carry runoff exceeding a given design flood.

Energy Dissipator - A device used to reduce the energy of flowing water.

Environment - The sum total of all the external conditions that may act on an organism or community to influence its development or existence.

Ephemeral Stream - A stream or portion of a stream that flows only in direct response to precipitation. It receives little or no water from springs and no long continued supply from snow or other sources. Its channel is at all times above the water table.

Erosion - 1. The wearing away of the land surface by running water, wind, ice, or other geological agents, including such processes as gravitational creep. 2. Detachment and movement of soil or rock fragments by water, wind, ice, or gravity. The following terms are used to describe different types of water erosion:

Accelerated Erosion - Erosion much more rapid than normal, natural, or geologic erosion, primarily as a result of the influence of the activities of man or, in some cases, of other animals or natural catastrophes that expose base surfaces, for example, fires.

Geological Erosion - The normal or natural erosion caused by geological processes acting over long geologic periods and resulting in the wearing away of mountains, the building up of floodplains, coastal plains, etc. Syn. natural erosion.

Gully Erosion - The erosion process whereby water accumulates in narrow channels and, over short periods, removes the soil from this narrow area to considerable depths, ranging from 1 to 2 feet to as much as 75 to 100 feet.

Natural Erosion - Wearing away of the earth's surface by water, ice, or other natural agents under natural environmental conditions of climate, vegetation, etc., undisturbed by man. Syn. geologic erosion.

Normal Erosion - The gradual erosion of land used by man that does not greatly exceed natural erosion. See natural erosion.

Rill Erosion - An erosion process in which numerous small channels only several inches deep are formed; occurs mainly on recently cultivated soils. See rill.

Sheet Erosion - The removal of a fairly uniform layer of soil from the land surface by runoff water.

Splash Erosion - The spattering of small soil particles caused by the impact of raindrops on wet soils. The loosened and spattered particles may or may not be subsequently removed by surface runoff.

Fauna - The animal life of a region.

Fertilizer - Any organic or inorganic material of natural or synthetic origin that is added to a soil to supply elements essential to plant growth.

Fertilizer Analysis - The percentage composition of a fertilizer expressed in terms of elemental nitrogen, phosphoric acid (P₂O₅) and potash (K₂O) or as elemental phosphorous (P) and potassium (K). Examples are 5-10-10, 10-10-10, 0-14-14, and 16-20-0. Minor elements are sometimes included also.

Filter Blanket - A layer of sand and /or gravel designed to prevent the movement of fine-grained soils.

Filter Strip - A long, narrow vegetative planting used to retard or collect sediment for the protection of diversions, drainage basins, or other structures.

Firm Soil - 1. A characteristic of soil between friable and hard 2. Soil that has been somewhat compressed by tillage operations when preparing a seedbed.

Flat - Section of stream with current too slow to be classed as a riffle and too shallow to be classed as a pool. Stream bottom usually composed of sand or finer materials, with coarse rubble, boulders, or bedrock occasionally evident.

Flood - An overflow or inundation that comes from a river or other body of water and causes or threatens damage.

Flood Control - Methods or facilities for reducing flood flows.

Flood Plain - The relatively flat area adjoining the channel of a natural stream that has been or may be hereafter, covered by floodwater.

Flood Routing - Determining the changes in the rise and fall of floodwater as it proceeds downstream through a valley or a reservoir.

Freeboard - The vertical distance between the maximum design water surface elevation and the top of a retaining bank or structure.

Frequency Curve - A graphical representation of the frequency of occurrence of specific events, such as flood peaks, precipitation amounts, annual or seasonal runoff, etc.

Friable Soil - Soil which is easily crumbled or tilled; a desirable characteristic of a soil often associated with good tilth but not necessarily with fertility.

Gabion - A galvanized wire basket filled with stone used for structural purposes. When fastened together used as retaining walls, revetments, slope protection and similar structures.

Gradation (geology) - The bringing of a surface or a streambed to grade, by running water. As used in connection with sedimentation and fragmental products for engineering evaluation, the term gradation refers to the frequency distribution of the various sized grains that constitute a sediment, soil, or other material.

Grade - 1. The slope of a road, channel, or natural ground. 2. Any surface prepared for the support of construction such as that for paving or laying a conduit.

Grade Stabilization Structure - A structure to stabilize the grade or to control head-cutting in natural or artificial channels.

Gradient - 1. Change of elevation, velocity, pressure, or other characteristics per unit length. 2. Slope or grade.

Grading - Any stripping, cutting, filling, stockpiling, or combination thereof which modifies the land surface.

Grass - Any member of the botanical family *Gramineae*; herbaceous plants with blade like leaves arranged in two ranks on a round to flattened stem. Common examples are fescue, bermudagrass, and bahiagrass. A term sometimes used to indicate a combination of grass and legumes grown for forage or turf purposes.

Grass Lined Channel - A natural or constructed waterway, usually broad and shallow, covered with erosion-resistant grasses, used to conduct surface water.

Ground Cover - Any vegetation producing mat on or just above the soil surface. In forestry, includes low-growing shrubs, vines, and herbaceous plants under the trees.

Gully - A channel or miniature valley cut by concentrated runoff but through which water commonly flows only during and immediately after heavy rains or during the melting of snow. A gully is a form of water erosion and is distinguished from a rill by the fact that it cannot be obliterated by normal farm tillage operations, whereas a rill can be eliminated by such tillage.

Gully Control Plantings - The planting of forage, legume, or woody plant seeds, seedlings, cuttings, or transplants in gullies to establish or re-establish a vegetative cover adequate to control runoff and erosion and incidentally produce useful products.

Habitat - The environment in which the life needs of a plant or animal are supplied.

Hard Seed - Live seed that is capable of growth but which is slow to germinate or start growth when growing conditions are optimum. This is due to the fact that the seeds do not readily absorb water or oxygen. Hard seed is especially common in the legume family.

Heavy Soil - A term often applied to soils which have a high silt or clay content and which are difficult to pulverize when tilled or excavated.

Heel-in - To store young trees and other plants in a temporary trench, covering the roots with soil, to keep them from drying out before they are permanently planted.

Helminths - A parasitic intestinal nematode.

Highway Erosion Control - The prevention and control of erosion in ditches, at cross drains, and on fills and road banks within a highway right-of-way. Includes vegetative practices and structural practices

Hood Inlet - A pipe entrance wherein the top edge of the pipe is extended 3/4 of the diameter beyond the bottom invert cut on an angle.

Hulled Seed - Seed from which the hull or other outer covering has been removed. Example: Hulled common Bermuda grass seed. Hulling usually reduces the amount of seed required to plant an area and encourages quick germination.

Hydraulic Radius - The cross-sectional area of a stream divided by its wetted perimeter. The "r" in Manning's formula.

Hydrograph - A graph showing for a given point on a stream or drainage system, the discharge, stage, velocity, or other property of water with respect to time.

Hydroseeding - A method of broadcasting seed and sometimes lime, fertilizer, and mulch together in a mixture of water.

Impact Basin - A device used to dissipate the energy of flowing water. Generally constructed of concrete in the form of a depressed and partially submerged vessel and may utilize baffles to dissipate velocities.

Inlet (hydraulics) - 1. A surface connection to a closed drain. 2. A structure at the diversion end of a conduit. 3. The upstream end of any structure through which water may flow.

Inoculant - A special culture of nitrogen-fixing bacteria used to treat legume seeds and thus ensure their nitrogen-fixing ability.

Intermittent Stream - A stream or portion of a stream that flows only in direct response to precipitation. It receives little or no water from springs and no long-continued supply

from melting snow or other sources. It is dry for a large part of the year, ordinarily more than 3 months.

Interseeding - Seeding into an established vegetation.

Invader Plant Species - Plant species that were absent in undisturbed portions of the original vegetation and will invade under disturbance or continued overuse. Commonly termed invaders.

Land - Any ground, soil, or earth including marshes, swamps, drainageways, and areas not permanently covered by water.

Land Capability - The suitability of land for use without permanent damage. Land capability, as ordinarily used in the United States, is an expression of the effect of physical land conditions, including climate, on the total suitability for use without damage for crops that require regular tillage, for grazing, for woodland, and for wildlife. Land capability involves consideration of (1) the risks of land damage from erosion and other causes and (2) the difficulties in land use owing to physical land characteristics, including climate.

Land Capability Class - One of the eight classes of land in the land capability classification of the Soil Conservation Service. These eight land capability classes, distinguished according to the risk of land damage or the difficulty of land use, are:

Land suitable for cultivation and other uses.

- I. Soils in class I have few limitations that restrict their use.
- II. Soils in class II have some limitations that reduce the choice of plants or require moderate conservation practices.
- III. Soils in class III have severe limitations that reduce the choice of plants or require special conservation practices, or both.
- IV. Soils in class IV have very severe limitations that restrict the choice of plants, require very careful management, or both.

Land generally not suitable for cultivation (without major treatment).

- V. Soils in class V have little or no erosion hazard but have other limitations, impractical to remove, that limit their use largely to pasture, range, woodland, or wildlife food and cover.

- VI. Soils in class VI have severe limitations that make them generally unsuited for cultivation and limit their use largely to pasture or range, woodland, or wildlife food and cover.
- VII. Soils in class VII have very severe limitations that make them unsuited to cultivation and that restricts their use largely to grazing, woodland, or wildlife.
- VIII. Soils and landforms in class VIII have limitations that preclude their use for commercial plant production and restrict their use to recreation, wildlife, water supply, or aesthetic purposes.

Land Resource Area - An area of land reasonably alike in its relationship to agriculture with emphasis on combinations and/or intensities of problems in soil and water conservation, ordinarily larger than a land resource unit and smaller than a land resource region.

Landscape - All the natural features, such as fields, hills, forests, water, etc., that distinguish one part of the earth's surface from another part, usually that portion of land or territory which the eye can comprehend in a single view, including all of its natural characteristics.

Land Use Plan - A community plan outlining proposed future land uses and their distribution.

Land Use Planning - The process by which decisions are made on future land uses over extended time periods that are deemed to best serve the general welfare. These decisions are best made by considering the resource capability of the land to support the type of use planned. Decision-making authorities on land uses are usually vested in state and local governmental units, but citizen participation in the planning process is essential for proper understanding and implementation.

Legume - A member of the botanical family *Leguminosae*. Some well known legumes are peas, beans, clovers, and sericea. Most legumes have the ability to take nitrogen from the air for use by plants, and many are important food, forage, and low-maintenance ground cover plants.

Level Spreaders - A shallow channel excavation at the outlet end of a diversion with a level section for the purpose of diffusing the diversion outflow.

Lime (agricultural) - Usually ground limestone applied as a soil amendment to correct the acidity of soil and provide calcium for plant growth. Dolomitic lime also provides magnesium. Other materials used for lime include basic slag, marl, and ground shells.

Liming - The application of lime to land, primarily to reduce soil acidity and supply calcium for plant growth. Dolomitic limestone supplies both calcium and magnesium.

May also improve soil structure, organic matter content, and nitrogen content of the soil by encouraging the growth of legumes and soil microorganisms. Liming an acid soil to a pH value of about 6.5 is desirable for maintaining a high degree of availability of most of the nutrient elements required by plants.

Liquid Limit - The moisture content at which the soil passes from a plastic to a liquid state. In engineering, a high liquid limit indicated that the soil has a high content of clay and a low capacity for supporting loads.

Loam - Technically, a soil textural class; but also a term used to designate topsoil, fertile and friable soils, and soils which are easily tilled.

Manning's Formula (hydraulics) - A formula used to predict the velocity of water flow in an open channel or pipeline:

$$V = \frac{1.486 r^{2/3} s^{1/2}}{n}$$

Where **V** is the main velocity of flow in feet per second, **r** is the hydraulic radius; **s** is the slope of the channel in feet per foot, and **n** is the roughness coefficient or retardance factor of the channel lining.

Marking Trees - Selection and indication, usually by blaze or paint spot, of trees to be cut or retained in a cutting operation.

Marsh - Periodically wet or continually flooded area with the surface not deeply submerged. Covered dominantly with sedges, cattails, rushes, or other hydrophytic plants. Subclasses include freshwater and saltwater marshes. See swamp; miscellaneous land type.

Meadow - An area of natural or planted vegetation dominated by grasses and grass-like plants used primarily for hay production.

Mine Dumps - Areas covered with overburden and other waste materials from ore and coal mines, quarries, and smelters, usually with little or no vegetative cover. A miscellaneous land type.

Mineral Soil - A soil consisting predominantly of, and having its properties determined predominantly by, mineral matter, usually containing less than 20 percent organic matter but sometimes containing an organic surface layer up to 30 centimeters thick. See organic soil.

Mulch or Mulching - Plant residues, natural, artificial, or other materials spread on the soil to reduce erosion, promote plant growth, conserve moisture, and to minimize temperature fluctuation.

Native Species - A species that is a part of an area's original fauna or flora.

Natural Area - 1. An area set aside indefinitely to preserve a representative unit of a major forest, range, or wetland type primarily for the purposes of science, research, or education. 2. A site or area in its natural state undisturbed by man's activities.

Natural Grassland - An area in which the natural potential plant community is dominated by grasses and grass-like plants. Associated species include forbs and woody plants.

Natural Revegetation - Natural re-establishment of plants; propagation of new-plants over an area by natural processes.

Neutral Soil - A soil that is neither acid nor alkaline; specifically, a soil with a pH of 7.0, but often those with a pH ranging between 6.6 and 7.3.

Nurse Crop - A fast-growing crop grown with a slow-growing crop to provide quick or temporary cover. An example is fast-growing rye planted with a slow-growing bahiagrass. Nurse crops are competitive and must be used with discretion.

Outfall - The point where water flows from a conduit, stream, or drain.

Outlet - The point of water disposal from a stream, river, lake, tidewater, or artificial drain.

Overfall - 1. An abrupt change in stream channel elevation. 2. The part of a dam or weir over which water flows.

Peak Discharge - The maximum instantaneous flow from a given storm condition at a specific location.

Periphyton - Plants growing on other plants, twigs, and stones in water.

Permissible Velocity (hydraulics) - The highest velocity at which water may be carried safely in a channel or other conduit.

pH - A numerical measure of the hydrogen ion concentration in the soil; a term used to indicate the acidity (pH below 7.0) or alkalinity (pH above 7.0) of soil. See acid soil.

Pipe Drop - A circular conduit used to convey water down steep grades.

Plant Material Center - A place where plants are assembled and their value and use in a conservation program is determined. This includes both domestic collections and plant introductions. Plants are assembled; their performance is evaluated; selections are made and increased for field testing; varieties are named and released; and foundation-quality seed and/or stock is produced and distributed to cooperative seed growers and nurseries for commercial production and use.

Plant Succession - The process of vegetation development whereby an area becomes successively occupied by different plant communities of higher ecological order.

Plasticity Index - The moisture content at which a soil changes from a semi-solid to a plastic state.

Playa - A shallow central basin of a plain where water gathers after a rain and is evaporated.

Plunge Pool - A device used to dissipate the energy of flowing water that may be constructed or made by the action of flowing. These facilities may be protected by various lining materials.

Pool - Section of stream deeper and usually wider than normal with appreciably slower current than immediate upstream or downstream areas, and possessing adequate cover (sheer depth or physical condition) for protection of fish. The stream bottom is usually a mixture of silt and coarse sand.

Principal Spillway - Generally constructed of permanent material and designed to regulate the normal water level, provide flood protection and reduce the frequency of operation of the emergency spillway.

Pure Live Seed - The product of the percentage of germination plus the hard seed and the percentage of pure seed, divided by 100.

Rainfall Intensity - The rate at which rain is falling at any given instant, usually expressed in inches per hour.

Recreation Area Planting - Establishing grasses, legumes, vines, shrubs, trees, or other plants on recreation areas.

Recreation Area Stabilization - Stabilizing recreation areas subject to heavy use by surfacing with suitable materials or by installing needed structures.

Recreation Land - Land and water used or usable primarily as sites for outdoor recreation facilities and activities.

Recreation Land Grading and Shaping - Altering the surface of land to meet the requirements of recreation facilities.

Recreation Trail and Walkway - A pathway prepared especially for pedestrian, equestrian, and cycle travel.

Renewable Natural Resources - Can be restored and improved to produce the things man needs.

Revetment - Facing of stone or other material, either permanent or temporary, placed along the edge of a stream to stabilize the bank and to protect it from the erosive action of the stream.

Ridge - The bank or dike constructed on the downslope side of a diversion.

Riffle - Section of stream containing gravel or rubble, in which surface water is at least slightly turbulent and current, is swift enough that the surface of the gravel and rubble is kept fairly free from sand and silt.

Rill - Small, intermittent water course with steep sides, usually only a few inches deep and, hence, no obstacle to tillage operations.

Riparian Rights - The rights of an owner whose land abuts water. They differ from state to state and often depend on whether the water is a river, lake, or ocean. See water rights.

Riprap - Broken rock, cobbles, or boulders placed on earth surfaces, such as the face of a dam or the bank of a stream, for protection against the action of water.

Riser - The inlet portion of a drop inlet spillway that extends vertically from the pipe conduit and controls the water surface elevation.

River Basin Plan - A plan for development of water and related land resources to make the best use of such resources to meet the basin needs and make the greatest long-term contribution to the economic growth and social well being of the people of the basin and the nation.

Root Zone - The part of the soil that is penetrated or can be penetrated by plant roots.

Roughness Coefficient (hydraulics) - A factor in velocity and discharge formulas representing the effect of channel roughness on energy losses in flowing water. Manning's "n" is a commonly used roughness coefficient.

Runoff - That portion of the precipitation that makes its way toward stream channels, lakes, or oceans as surface or subsurface flow. When the term "runoff" is used alone, surface runoff usually is implied.

Rural Beautification - Creating, enhancing, and preserving natural beauty in the countryside.

Sand - 1. A soil textural class including soil particles between 0.05 and 2.0 millimeters in diameter. 2. A term sometimes used to indicate sediment.

Scalping - Removal of sod or other vegetation in spots or strips.

Scarified Seed - Seed that has had the hard outer coat scuffed or otherwise treated to improve absorption of moisture and thus facilitate germination. Example: scarified sericea lespedeza seed. Scarified seed require lower seeding rates than unscarified seed, but must be planted closer to optimum seeding dates.

Scarify - To abrade, scratch, or modify the surface. For example, to scratch the impervious seed coat of hard seed or to break the surface of the soil with a narrow-bladed implement.

Scour - To abrade and wear away. Used to describe the wearing away of terrace or diversion channels or streambeds.

Sediment - Solid soil material, both mineral and organic, that is being moved or has been moved from its original site by wind, gravity, flowing water or ice. Also, sometimes referred to as silt or sand.

Sediment Basin - A depression formed by the construction of a barrier or dam built at suitable locations to retain rock, sand, gravel, silt or other material.

Sediment Discharge - The quantity of sediment, measured in dry weight or by volume, transported through a stream cross-section in a given time. It consists of both suspended load and bed-load.

Seedbed - Soil prepared to receive seed and promote the growth of seedlings. The term may apply also to prepared soil in which plants are to be planted by sprigging, sodding, or other means.

Seed Purity - The percentage of the desired species in relation to the total quantity, including other species, weed seed, and foreign matter.

Sheet Flow - Water, usually storm runoff, flowing in a thin layer over the ground surface. Syn. overland flow.

Shrub - A woody perennial plant differing from a perennial herb by its more woody stems and from a tree by its low stature and habit of branching from the base. There is no definite line between herbs and shrubs or between shrubs and trees; all possible intergradations occur.

Side Slopes - The slopes of the sides of a canal, dam, or embankment.

Silt - 1. A soil textural class including soil particles between 0.05 and 0.002 millimeters in diameter. 2. A term often used to indicate sediment.

Sink - Depression in the land surface; a negative potential area, as in a source and a sink.

Site (ecology) - 1. An area considered for its ecological factors with reference to capacity to produce vegetation; the combination of biotic, climatic, and soil conditions of an area. 2. An area sufficiently uniform in soil, climate, and natural biotic conditions to produce a particular climax vegetation.

Sod - 1. Established grass, turf, or sward. 2. Thin rectangles, strips or pieces of earth and matted grass roots and stems that are transplanted to establish grass cover.

Sod Grasses - Stoloniferous or rhizomatous grasses that form a sod or turf.

Soil - The unconsolidated mineral and organic material on the immediate surface of the earth that serves as a natural medium for the growth of land plants.

Soil Horizon - A layer of soil, approximately parallel to the surface, that has distinct characteristics produced by soil-forming processes.

Soil Profile - A vertical cross-section of soil layers constitutes the soil profile, which is composed of three major layers designated, A, B, and C horizons. The A and B horizons are layers that have been modified by weathering, while the C horizon is unaltered by soil-forming processes.

A horizon: The original top layer of soil having the same color and texture throughout its depth. It is usually 10 to 12 inches thick but may range from 2 inches to 2 feet. The A horizon is also referred to as the topsoil or surface soil when erosion has not taken place.

B horizon: The soil layer just below the A horizon that has about the same color and texture throughout its depth. It is usually 10 to 12 inches thick but may range from 4 inches to 8 feet. The B horizon is also referred to as the subsoil.

C horizon: The soil layer just below the B horizon having about the same color and texture throughout its depth. It is quite different from the B horizon. It may be of indefinite thickness. At the beginning of the soil profile development, the C horizon constituted the entire depth, but time, weather, and soil-forming processes have changed the top layers into the A and B horizons described above.

Spillway - An open or closed conduit used to convey water from a reservoir.

Spillway (emergency) - A spillway used to carry runoff exceeding a given design flood; commonly, a channel around the end of a dam built to carry off excess floodwaters.

Spillway (primary) - A spillway used to convey the runoff of a given designed flood; commonly, a metal pipe or concrete riser connected to a closed conduit under a dam which discharges runoff from a given flood.

Sprig - Portions of stems and roots of grasses that are planted to provide rapid ground cover or assure trueness to type.

Sprigging - The planting of a portion of the stem and root of grass.

Sprinkler Systems - All sprinkler lines, main lines, submains, pumping plant, operation control equipment, and other accessories required for applying water to a field by the sprinkler method.

Stabilized Center Section - An area in the bottom of a grassed waterway protected by stone, asphalt, concrete, or other materials to prevent erosion.

Stilling Basin - An open structure or excavation at the foot of an overfall, chute, drop, or spillway to reduce the energy of the descending stream.

Stone Center - A stabilized center section made of stone.

Storm Frequency - An expression or measure of how often a hydrologic event of given size or magnitude should on an average be equaled or exceeded. The average should be based on a reasonable example.

Streambanks - The usual boundaries (not the flood boundaries) of a stream channel. Right and left banks are indicated when facing downstream.

Subsoil - The layers of soil beneath the topsoil. A term sometimes used to indicate soil of low quality for vegetative purposes.

Succession - The progressive development of vegetation toward its highest ecological expression, the climax; replacement of one plant community by another.

Suitable Outlet - An outlet, either natural or artificial, that will dispose of water at non-erosive velocities and without flooding.

Temporary Protection - Stabilization of erosive or sediment-producing areas.

Tidal Marsh - A low, flat area traversed by interlacing channels and tidal sloughs and periodically inundated by high tides. Vegetation usually consists of salt-tolerant plants.

Toe Drain - A drainage system constructed in the downstream portion of an earth dam or levee to prevent excessive hydrostatic pressures.

Topsoil - 1. A vague term applied to the upper layer of soil. 2. The "plow layer" or upper 6 to 8 inches of soil. 3. The "A" horizons of a soil. 4. A term used to indicate friable, fertile soil applied over other soil to improve conditions for plant growth.

Toxic Salt Reduction - Decreasing harmful concentrations of toxic salts in soils, usually by leaching and with, or without, the addition of soil amendments.

Trash Rack - A structural device used to prevent debris from entering a spillway or other hydraulic structure.

Tributary - Secondary branch of a stream, drain, or other channel that contributes flow to the primary or main channel.

Unhulled Seed - Seed from which the hull or outer covering has not been removed. Example: Unhulled Bermudagrass seed. Unhulled seed can sometimes be used to an

advantage but is slower to germinate and requires a higher seeding rate than hulled seed.

Unified Soil Classification System - A classification system based on the identification of soils according to their particle size, gradation, plasticity index, and liquid limit.

Universal Soil Loss Equation - An equation used for the design of water erosion control systems: $A = RKLSPC$ wherein **A** = average annual soil loss in tons per acre per year; **R** = rainfall factor; **K** = soil erodibility factor; **L** = length of slope; **S** = percent of slope; **P** = conservation practice factor; and **C** = cropping and management factor. (**T** = soil loss tolerance value that has been assigned each soil, expressed T/A/Year.)

Unscarified Seed - Seed that has not had the hard outer coat scuffed or otherwise treated to improve germination. Example: unscarified sericea lespedeza. Unscarified seed will germinate but exposure to winter temperatures or special treatment is necessary to break its dormancy. This is an advantage when an area must be seeded "off season."

Uplift Forces - Vertical pressures acting upward on a structure, usually caused by a buoyant condition.

Vegetative Cover - All plants of all sizes and species found on an area, irrespective of whether they have forage or other value. Syn. plant cover.

Vegetative Protection - Stabilization of erosive or sediment producing areas by covering the soil with:

- a. Permanent seeding, producing long-term vegetative cover.
- b. Short-term seeding, producing temporary vegetative cover.
- c. Sodding, producing areas covered with a turf of perennial sod-forming grass.

Velocity - The rate of flow measured in feet per second.

Watercourse - A natural or constructed channel for the flow of water.

Water Disposal System - A complete system for safely removing excess water from land. On sloping lands, a system may include diversions, grassed waterways, grade stabilization structures, and other practices. Systems on flat lands may consist of surface or subsurface drains, land leveling, and other measures.

Water Rights - The legal rights to the use of water. They consist of riparian rights and those acquired by appropriation and prescription. Riparian rights are those rights to use and control water by virtue of ownership of the bank or banks. Appropriated rights are those acquired by an individual to the exclusive use of water, based strictly on priority of appropriation and application of the water to beneficial use and without limitation of the place of use to riparian land. Prescribed rights are those to which legal title is acquired by long possession and use without protest of other parties.

Watershed - See Drainage Area.

Watershed Area - All land and water within the confines of a drainage divide or a water problem area consisting in whole or in part of land needing drainage or irrigation.

Watershed Management - The use, regulation, and treatment of water and land resources of a watershed to accomplish stated objectives.

Water Table - The upper surface of ground water or the level below which the soil is saturated with water.

Waterway - A natural or constructed channel for the safe disposal of excess water from a field or diversion. Waterways are usually located on sloping ground and must be established in grass to prevent erosion.

Weep-holes (engineering) - Openings left in retaining walls, aprons, linings, or foundations to permit drainage and reduce pressure.

Wetted Perimeter - The length of the wetted contact between a liquid and its containing conduit, measured along a plane at right angles to the direction of flow.

Windbreak - 1. A living barrier of trees or combination of trees and shrubs located adjacent to farm or ranch headquarters and designed to protect the area from cold or hot winds and drifting snow. Also headquarters and livestock windbreaks. 2. A narrow barrier of living trees or combination of trees and shrubs, usually from one to five rows, established within or around a field for the protection of land and crops. May also consist of narrow strips of annual crops, such as corn or sorghum.

Wind Erosion - The detachment and transportation of soil by wind.

Wind Erosion Equation - An equation used for the design of wind erosion control systems. $E = f(IKCLV)$ wherein **E** = average annual soil loss, expressed in tons per acre per year; **f** = a function of; **I** = soil erodibility; **K** = soil ridge roughness; **C** = climatic factor; **L** = unsheltered distance across the field along the wind erosion direction; and **V** = vegetative cover.

Woodland - Any land used primarily for growing trees and shrubs. Woodland includes, in addition to what is ordinarily termed "forest" or "forest plantations," shelterbelts, windbreaks, wide hedgerows containing woodland species for wildlife food or cover, stream and other banks with woodland cover, etc. It also includes farmland and other lands on which woody vegetation is to be established and maintained.

Zoning (rural) - A means by which governmental authority is used to promote the proper use of land under certain circumstances. This power traditionally resides in the state, and the power to regulate land use by zoning is usually delegated to minor units of government, such as town, municipalities, and counties, through an enabling act that specifies powers granted and the conditions under which these are to be exercised.

Zoning Ordinance – An ordinance based on the police power of government to protect the public health, safety, and general welfare. It may regulate the type of use and intensity of development of land and structures to the extent necessary for a public purpose. Requirements may vary among various geographically defined areas called zones. Regulations generally cover such items as height and bulk of buildings, density of dwelling units, off-street parking, control of signs, and use of land for residential, commercial, industrial, or agricultural purposes. It may also contains provisions to protect natural resources, such as soil erosion and sediment control, and protection of steep slopes, trees, and wetlands. A zoning ordinance is one of the major methods for implementation of the comprehensive plan.

APPENDIX A - NATIONAL POLLUTANT DISCHARGE ELIMINATION SYSTEM (NPDES) PERMITS FOR CONSTRUCTION SITE STORM WATER DISCHARGES

INTRODUCTION

This appendix contains information on the National Pollutant Discharge Elimination System (NPDES) permits for construction site storm water discharges in the state of Illinois. It contains a general overview of the program, the NPDES Permit No. ILR10 Construction Site Activities, the Notice of Intent (NOI) form, the Incidence of Non-Compliance (ION) form, and the Notice of Termination (NOT) form. The NOI, ION, and NOT forms are in a read-only pdf file format, but word fillable forms are available on the CD in the IEPA Fillable Forms folder.

These materials have been provided by the Illinois Environmental Protection Agency (EPA) who is responsible for administering the program in Illinois. Questions about the program should be directed to the Illinois EPA-Division of Water Pollution Control - Permit Section #15, Bureau of Water, 1021 North Grand Avenue East, P.O. Box 19276, Springfield, IL 62794-9276, phone 217-782-0610, fax 217-782-9891.

The Permit Section website contains information on when a permit is needed, forms, and a list of contacts at Illinois EPA: <http://www.epa.state.il.us/water/permits/waste-water/index.html>

The NPDES Permit No. ILR10, and the NOI, ION, and NOT forms are in a read-only format.

This section was updated in April 2000.

NATIONAL POLLUTANT DISCHARGE ELIMINATION SYSTEM (NPDES) PERMITS FOR CONSTRUCTION SITE STORM WATER DISCHARGES

General

Under the provisions of the Clean Water Act Amendments of 1987 and the federal regulations at 40 CFR Part 122.26(b)(14)(x), operators of construction sites are required to have NPDES permits for the discharge of storm water except "...operations that result in the disturbance of less than five acres of total land area which are not part of a larger common plan of development or sale." The following are the definitions that the United States Environmental Protection Agency (USEPA) uses for "operators" and "part of a larger common plan of development or sale".

- The operator is determined by who has day to day supervision and control of the activities occurring at a site. In some cases, the operator may be the owner or the developer; at other sites the operator may be the general contractor. The operator is responsible for applying for the permit. In the case of construction, the owner may submit an application for a construction activity if the operators have not yet been identified. However, once the operators have been identified, they must become either sole permittees or co-permittees with the owner.
- A "larger common plan of development or sale" is a contiguous area where multiple separate and distinct construction activities may be taking place at different times on different schedules under one plan. For example, if a developer buys a 20 acre lot and builds roads, installs pipes, and runs electricity with the intention of constructing homes or other structures sometime in the near future, this would be considered a common plan of development or sale. If the land is parceled off or sold, and construction occurs on plots that are less than five acres by separate, independent builders, this activity still would be subject to storm water permitting requirements because USEPA considers it to be part of a larger plan of development (please note that the homes must have been included on the original site plan in order to trigger permit application requirements).

The Illinois General Permit for Construction Site Storm Water Discharges

The Illinois Environmental Protection Agency has issued an NPDES general permit for discharges from construction site activities. The major features of the Illinois permit are the following:

- The permit can authorize all discharges of storm water from construction sites anywhere in Illinois regardless of the size of the site.
- Part II of the permit contains detailed instructions on how to apply for coverage under the permit.
- The permit requires each construction site to have a storm water pollution prevention plan prior to the start of construction. Part IV of the permit contains information on how to develop a plan, what elements must be included in the plan, and what the periodic inspection requirements are.

- A copy of the storm water pollution prevention plan must be retained at the construction site from the date of project initiation to the date of final stabilization.
- The permittee is required to have qualified personnel inspect the disturbed areas of the construction site that have not been finally stabilized, structural control measures, and locations where vehicles enter or exit the site at least once every seven calendar days and within 24 hours of the end of a storm that is 0.5 inches of rain or greater or an equivalent snowfall.
- The permittee is required to submit within 5 days an "Incidence of Noncompliance" (ION) report for any violation of the storm water pollution prevention plan observed during an inspection conducted, including those not required by the Plan. The submission is required to be on an ION form and must include specific information on the cause of noncompliance, actions which were taken to prevent any further incidents of noncompliance, and a statement detailing any environmental impact which may have resulted from the noncompliance
- The storm water pollution prevention plan, inspection records and other information must be retained for a period of at least three years from the date that the site is finally stabilized.
- The permit expires on May 31, 2003, but site operators covered by the permit do not have to apply for coverage under the reissued permit since discharges covered under the expiring permit are automatically covered under the reissued permit.

The Phase II Storm Water Program

On December 8, 1999 USEPA published final regulations for Phase II of the NPDES storm water program. The new regulations reduce the size of sites that are required to have permits from five acres or more to one acre or more. The larger common plan of development or sale requirement remains unchanged, so a construction project that is less than one acre would need a permit if it was part of a larger common plan of development or sale that would ultimately result in the disturbance of one acre or more. The one acre requirement is effective as of March 10, 2003, and operators of construction sites that result in a total land disturbance of one acre or more must apply for permit coverage on or before March 10, 2003.

How to Obtain Coverage Under the Permit

To obtain coverage under the permit the operator must complete the one-page Notice of Intent (NOI) form, sign it, and send the original signed copy to the Illinois EPA. Unless notified by the Agency to the contrary, coverage under the permit is automatic, and operators are authorized to discharge storm water from construction sites under the terms and conditions of the permit either:

- 48 hours after the date the NOI is postmarked, if the project had established compliance with Illinois law regarding historic preservation and endangered species prior to submittal of the NOI;

or

- 30 days after the date the NOI is postmarked, if the project had not established compliance with Illinois historic preservation and endangered species requirements prior to submittal of the NOI.

The Agency will confirm the permit coverage and the project's permit number by letter approximately one week after the automatic coverage takes effect.

Termination of Coverage Under the Permit

After the land disturbing activities are complete and the site has been finally stabilized the operator should terminate his coverage under the permit by completing a Notice of Termination form and submitting it to the Agency. USEPA considers that a site has been finally stabilized when all land disturbing activities are complete and a uniform perennial vegetative cover with a density of 70 percent of the cover for unpaved areas and areas not covered by permanent structures has been established or equivalent permanent stabilization measures have been used.

CONSTRUCTION SITE ACTIVITIES

NATIONAL POLLUTANT DISCHARGE ELIMINATION SYSTEM (NPDES) Storm Water Permit

Expiration Date: May 31, 2003

Issue Date: May 14, 1998

Effective Date: June 1, 1998

In compliance with the provisions of the Illinois Environmental Protection Act, the Illinois Pollution Control Board Rules and Regulations (35 Ill. Adm. Code, Subtitle C, Chapter I), and the Clean Water Act, and the regulations thereunder the following discharges are authorized by this permit, in accordance with the conditions and attachments herein:

Thomas G. McSwiggin, P.E.
Manager, Permit Section
Division of Water Pollution Control

Part I. COVERAGE UNDER THIS PERMIT

A. **Permit Area.** The permit covers all areas of the State of Illinois with discharges to any waters of the State.

B. **Eligibility.**

1. This permit shall authorize all discharges of storm water associated with industrial activity from construction sites, (those sites or common plans of development or sale that will result in the disturbance of five or more acres total land area), (heretofore referred to as storm water discharges from construction activities) occurring after the effective date of this permit (including discharges occurring after the effective date of this permit where the construction activity was initiated before the effective date of this permit), except for discharges identified under paragraph I.B.3 (Limitations on Coverage).
2. This permit may only authorize a storm water discharge associated with industrial activity from a construction site that is mixed with a storm water discharge from an industrial source other than construction, where:
 - a. the industrial source other than construction is located on the same site as the construction activity;
 - b. storm water discharges associated with industrial activity from the areas of the site where construction activities are occurring are in compliance with the terms of this permit; and
 - c. storm water discharges associated with industrial activity from the areas of the site where industrial activity other than construction are occurring (including storm water discharges from dedicated asphalt plants and dedicated concrete plants) are covered by a different NPDES general permit or individual permit authorizing such discharges.
3. **Limitations on Coverage.** The following storm water discharges from construction sites are not authorized by this permit:
 - a. storm water discharges associated with industrial activity that originate from the site after construction activities have been completed and the site has undergone final stabilization.
 - b. discharges that are mixed with sources of non-storm water other than discharges identified in Part III.A (Prohibition on Non-Storm Water Discharges) of this permit and in compliance with paragraph IV.D.5 (Non-Storm Water Discharges) of this permit.
 - c. storm water discharges associated with industrial activity that are subject to an existing NPDES individual or general permit or which are issued a permit in accordance with Part VI.N (Requiring an Individual Permit or an Alternative General Permit) of this permit. Such discharges may be authorized under this permit after an existing permit expires provided the existing permit did not establish numeric limitations for such discharges; and
 - d. storm water discharges from construction sites that the Agency has determined to be or may reasonably be expected to be contributing to a violation of a water quality standard.

- e. Storm water discharges that the Agency, at its discretion, determines are not appropriately authorized or controlled by this general permit.

C. Authorization.

1. In order for storm water discharges from construction sites to be authorized to discharge under this general permit a discharger must submit a Notice of Intent (NOI) in accordance with the requirements of Part II below, using an NOI from provided by the Agency, or be covered by a valid Illinois General NPDES Construction Site Activities Permit.
2. Where a new operator (contractor) is selected after the submittal of an NOI under Part II below, a new Notice of Intent (NOI) must be submitted by the owner in accordance with Part II.
3. For projects that have complied with State law on historic preservation and endangered species prior to submittal of the NOI, through coordination with the Illinois Historic Preservation Agency and the Illinois Department of Natural Resources or through fulfillment of the terms of interagency agreements with those agencies, the NOI shall indicate that such compliance has occurred.

Unless notified by the Agency to the contrary, dischargers who submit an NOI in accordance with the requirements of this permit are authorized to discharge storm water from construction sites under the terms and conditions of this permit either:

- a. 48 hours after the date the NOI is postmarked, if the project had established compliance with Illinois law regarding historic preservation and endangered species prior to submittal of the NOI;
or
- b. 30 days after the date the NOI is postmarked, if the project had not established compliance with Illinois historic preservation and endangered species requirements prior to submittal of the NOI.

The Agency may deny coverage under this permit and require submittal of an application for an individual NPDES permit based on a review of the NOI or other information.

Part II. NOTICE OF INTENT REQUIREMENTS

A. Deadlines for Notification.

1. To receive authorization under this general permit, a discharge must either be covered by a valid Illinois General NPDES Construction Site Permit, or a Notice of Intent (NOI) in accordance with the requirements of this part must be submitted prior to the commencement of construction. For projects that have established compliance with Illinois law regarding historic preservation and endangered species prior to submittal of the NOI, the NOI must be submitted at least 48 hours prior to the commencement of construction. For all other projects, the NOI must be submitted at least 30 days prior to the commencement of construction.
2. Discharges that are covered by a valid Illinois General NPDES Construction Site Activities Permit are automatically covered by this permit.
3. A discharger may submit an NOI in accordance with the requirements of this part after the start of construction. In such instances, the Agency may bring an enforcement action for any discharges of storm water associated with industrial activity from a construction site that have occurred on or after the start of construction.

B. Failure to Notify. Dischargers who fail to notify the Agency of their intent to be covered, and discharge storm water associated with construction site activity to Waters of the State without an NPDES permit, are in violation of the Environmental Protection Act and Clean Water Act.

C. Contents of Notice of Intent. The Notice of Intent shall be signed in accordance with Part VI.G (Signatory Requirements) of this permit by all of the entities identified in paragraph 2 below and shall include the following information:

1. The mailing address, and location of the construction site for which the notification is submitted. Where a mailing address for the site is not available, the location can be described in terms of the latitude and longitude of the approximate center of the facility to the nearest 15 seconds, or the nearest quarter section (if the section, township and range is provided) that the construction site is located in;
2. The owner's name, address, telephone number, and status as Federal, State, private, public or other entity.
3. The name, address and telephone number of the general contractor(s) that have been identified at the time of the NOI submittal;
4. The name of the receiving water(s), or if the discharge is through a municipal separate storm sewer, the name of the municipal operator of the storm sewer and the ultimate receiving water(s);
5. The number of any NPDES permit for any discharge (including non-storm water discharges) from the site that is currently authorized by an NPDES permit.
6. A yes or no indication of whether the owner or operator has existing quantitative data which describes the concentration of pollutants in storm water discharges (existing data should not be included as part of the NOI); and
7. A brief description of the project, estimated timetable for major activities, estimates of the number of acres of the site on which soil will be disturbed, and a certification that a storm water pollution prevention plan has been prepared for the facility in accordance with Part IV of this permit, and such plan provides compliance with local sediment and erosion plans or permits and/or storm water management plans or permits in accordance with paragraph VI.G.1 (Signatory Requirements) of this permit. **(A copy of the plans or permits should not be included with the NOI submission).**

D. Where to Submit

1. Facilities which discharge storm water associated with construction site activity must use a NOI form provided by the Agency. NOIs must be signed in accordance with Part VI.G (Signatory Requirements) of this permit. NOIs are to be submitted certified mail to the Agency at the following address:

Illinois Environmental Protection Agency
 Division of Water Pollution Control
 Attention: Permit Section
 1021 North Grand East
 Post Office Box 19276
 Springfield, Illinois 62794-9276

2. A copy of the letter of notification of coverage or other indication that storm water discharges from the site are covered under an NPDES permit shall be posted at the site in a prominent place for public viewing (such as alongside a building permit).

E. Additional Notification. Facilities which are operating under approved local sediment and erosion plans, grading plans, or storm water management plans, in addition to filing copies of the Notice of Intent in accordance with Part D above, shall also submit signed copies of the Notice of Intent to the local agency approving such plans in accordance with the deadlines in Part A above. See Part IV.D.2.d (Approved State or Local Plans).

F. Notice of Termination. Where a site has been finally stabilized and all storm water discharges from construction sites that are authorized by this permit are eliminated, the permittee of the facility may submit a Notice of Termination that is signed in accordance with Part VI.G (Signatory Requirements) of this permit.

1. The Notice of Termination shall include the following information:

- a. The mailing address, and location of the construction site for which the notification is submitted. Where a mailing address for the site is not available, the location can be described in terms of the latitude and longitude of the approximate center of the facility to the nearest 15 seconds, or the nearest quarter section (if the section, township and range is provided) that the construction site is located in;
- b. The owner's name, address, telephone number, and status as Federal, State, private, public or other entity.
- c. The name, address and telephone number of the general contractor(s);
- d. The following certification signed in accordance with Part VI.G (Signatory Requirements) of this permit:

"I certify under penalty of law that all storm water discharges associated with construction site activity from the identified facility that are authorized by NPDES general permit ILR100000 have otherwise been eliminated. I understand that by submitting this notice of termination, that I am no longer authorized to discharge storm water associated with construction site activity by the general permit, and that discharging pollutants in storm water associated with construction site activity to Waters of the State is unlawful under the Environmental Protection Act and Clean Water Act where the discharge is not authorized by a NPDES permit. I also understand that the submittal of this notice of termination does not release an operator from liability for any violations of this permit or the Clean Water Act."

For the purposes of this certification, elimination of storm water discharges associated with industrial activity means that all disturbed soils at the identified facility have been finally stabilized and temporary erosion and sediment control measures have been removed or will be removed at an appropriate time, or that all storm water discharges associated with construction activities from the identified site that are authorized by a NPDES general permit have otherwise been eliminated.

2. All Notices of Termination are to be sent, using the form provided by the Agency to the address in paragraph II.D.1.

Part III. SPECIAL CONDITIONS, MANAGEMENT PRACTICES, AND OTHER NON-NUMERIC LIMITATIONS

A. Prohibition on Non-Storm Water Discharges.

1. Except as provided in paragraph I.B.2 and 2 below, all discharges covered by this permit shall be composed entirely of storm water.
2.
 - a. Except as provided in paragraph b below, discharges of materials other than storm water must be in compliance with a NPDES permit (other than this permit) issued for the discharge.
 - b. The following non-storm water discharges may be authorized by this permit provided the non-storm water component of the discharges is in compliance with paragraph IV.D.5 (Non-Storm Water Discharges): discharges from fire fighting activities; fire hydrant flushings; waters used to wash vehicles or control dust; potable water sources including waterline flushings; irrigation drainages; routine external building washdown which does not use detergents; pavement washwaters where spills or leaks of toxic or hazardous materials have not occurred (unless all spilled material has been removed) and where detergents are not used; air conditioning condensate; springs; uncontaminated ground water; and foundation or footing drains where flows are not contaminated with process materials such as solvents.

Part IV. STORM WATER POLLUTION PREVENTION PLANS

A storm water pollution prevention plan shall be developed for each construction site covered by this permit. Storm water pollution prevention plans shall be prepared in accordance with good engineering practices. The plan shall identify potential sources of pollution which may reasonably be expected to affect the quality of storm water discharges associated with construction site activity from the facility. In addition, the plan shall describe and ensure the implementation of practices which will be used to reduce the pollutants in storm water discharges associated with construction site activity and to assure compliance with the terms and conditions of this permit. Facilities must implement the provisions of the storm water pollution prevention plan required under this part as a condition of this permit.

A. Deadlines for Plan Preparation and Compliance.

The plan shall:

1. Be completed prior to the start of the construction to be covered under this permit and updated as appropriate;
2. Provide for compliance with the terms and schedule of the plan beginning with the initiation of construction activities.

B. Signature and Plan Review.

1. The plan shall be signed in accordance with Part VI.G (Signatory Requirements), and be retained on-site at the facility which generates the storm water discharge in accordance with Part VI.E (Duty to Provide Information) of this permit.
2. The permittee shall make plans available upon request from this Agency or a local agency approving sediment and erosion plans, grading plans, or storm water management plans; or in the case of a storm water discharge associated with industrial activity which discharges through a municipal separate storm sewer system with an NPDES permit, to the municipal operator of the system.
3. The Agency may notify the permittee at any time that the plan does not meet one or more of the minimum requirements of this Part. Such notification shall identify those provisions of the permit which are not being met by the plan, and identify which provisions of the plan requires modifications in order to meet the minimum requirements of this part. Within 7 days from receipt of notification from the Agency, the permittee shall make the required changes to the plan and shall submit to the Agency a written certification that the requested changes have been made. Failure to comply shall terminate authorization under this permit.
4. All storm water pollution prevention plans required under this permit are considered reports that shall be available to the public under Section 308(b) of the CWA. The permittee shall make plans available to members of the public upon request by the public. However, the permittee may claim any portion of a storm water pollution prevention plan as confidential in accordance with 40 CFR Part 2.

C. Keeping Plans Current. The permittee shall amend the plan whenever there is a change in design, construction, operation, or maintenance, which has a significant effect on the potential for the discharge of pollutants to the Waters of the State and which has not otherwise been addressed in the plan or if the storm water pollution prevention plan proves to be ineffective in eliminating or significantly minimizing pollutants from sources identified under paragraph D.2 below, or in otherwise achieving the general objectives of controlling pollutants in storm water discharges associated with construction site activity. In addition, the plan shall be amended to identify any new contractor and/or subcontractor that will implement a measure of the storm water pollution prevention plan. Amendments to the plan may be reviewed by the Agency in the same manner as Part IV.B above.

D. Contents of Plan. The storm water pollution prevention plan shall include the following items:

1. **Site Description.** Each plan shall, provide a description of the following:
 - a. A description of the nature of the construction activity;
 - b. A description of the intended sequence of major activities which disturb soils for major portions of the site (e.g. grubbing, excavation, grading);
 - c. Estimates of the total area of the site and the total area of the site that is expected to be disturbed by excavation, grading, or other activities;
 - d. An estimate of the runoff coefficient of the site after construction activities are completed and existing data describing the soil or the quality of any discharge from the site;
 - e. A site map indicating drainage patterns and approximate slopes anticipated before and after major grading activities, locations where vehicles enter or exit the site and controls to prevent offsite sediment tracking, areas of soil disturbance, the location of major structural and nonstructural controls identified in the plan, the location of areas where stabilization practices are expected to occur, surface waters (including wetlands), and locations where storm water is discharged to a surface water; and
 - f. The name of the receiving water(s) and the ultimate receiving water(s), and areal extent of wetland acreage at the site.
2. **Controls.** Each plan shall include a description of appropriate controls that will be implemented at the construction site. The plan will clearly describe for each major activity identified in paragraph D.1 above, appropriate controls and the timing during the construction process that the controls will be implemented. (For example, perimeter controls for one portion of the site will be installed after the clearing and grubbing necessary for installation of the measure, but before the clearing and grubbing for the remaining portions of the site. Perimeter controls will be actively maintained until final stabilization of those portions of the site upward of the perimeter control. Temporary perimeter controls will be removed after final stabilization). The description of controls shall address as appropriate the following minimum components:

a. **Erosion and Sediment Controls.**

(i). **Stabilization Practices.** A description of interim and permanent stabilization practices, including site-specific scheduling of the implementation of the practices. Site plans should ensure that existing vegetation is preserved where attainable and that disturbed portions of the site are stabilized. Stabilization practices may include: temporary seeding, permanent seeding, mulching, geotextiles, sod stabilization, vegetative buffer strips, protection of trees, preservation of mature vegetation, and other appropriate measures. A record of the dates when major grading activities occur, when construction activities temporarily or permanently cease on a portion of the site, and when stabilization measures are initiated shall be included in the plan. Except as provided in paragraphs (A) and (B) below, stabilization measures shall be initiated as soon as practicable in portions of the site where construction activities have temporarily or permanently ceased, but in no case more than 14 days after the construction activity in that portion of the site has temporarily or permanently ceased.

(A). Where the initiation of stabilization measures by the 14th day after construction activity temporary or permanently cease is precluded by snow cover, stabilization measures shall be initiated as soon as practicable.

(B). Where construction activity will resume on a portion of the site within 21 days from when activities ceased, (e.g. the total time period that construction activity is temporarily ceased is less than 21 days) then stabilization measures do not have to be initiated on that portion of site by the 14th day after construction activity temporarily ceased.

(ii). **Structural Practices.** A description of structural practices to the degree attainable, to divert flows from exposed soils, store flows or otherwise limit runoff and the discharge of pollutants from exposed areas of the site. Such practices may include silt fences, earth dikes, drainage swales, sediment traps, check dams, subsurface drains, pipe slope drains, level spreaders, storm drain inlet protection, rock outlet protection, reinforced soil retaining systems, gabions, and temporary or permanent sediment basins. Structural practices should be placed on upland soils to the degree attainable. The installation of these devices may be subject to Section 404 of the CWA.

b. **Storm Water Management.** A description of measures that will be installed during the construction process to control pollutants in storm water discharges that will occur after construction operations have been completed. Structural measures should be placed on upland soils to the degree attainable. The installation of these devices may be subject to Section 404 of the CWA. This permit only addresses the installation of storm water management measures, and not the ultimate operation and maintenance of such structures after the construction activities have been completed and the site has undergone final stabilization. Permittees are responsible for only the installation and maintenance of storm water management measures prior to final stabilization of the site, and are not responsible for maintenance after storm water discharges associated with industrial activity have been eliminated from the site.

(i). Such practices may include: storm water detention structures (including wet ponds); storm water retention structures; flow attenuation by use of open vegetated swales and natural depressions; infiltration of runoff onsite; and sequential systems (which combine several practices). The pollution prevention plan shall include an explanation of the technical basis used to select the practices to control pollution where flows exceed predevelopment levels.

(ii). Velocity dissipation devices shall be placed at discharge locations and along the length of any outfall channel as necessary to provide a non-erosive velocity flow from the structure to a water course so that the natural physical and biological characteristics and functions are maintained and protected (e.g. maintenance of hydrologic conditions, such as the hydroperiod and hydrodynamics present prior to the initiation of construction activities).

c. **Other Controls.**

(i). **Waste Disposal.** No solid materials, including building materials, shall be discharged to Waters of the State, except as authorized by a Section 404 permit.

(ii). The plan shall ensure and demonstrate compliance with applicable State and/or local waste disposal, sanitary sewer or septic system regulations.

d. **Approved State or Local Plans.**

(i). The management practices, controls and other provisions contained in the storm water pollution prevention plan must be at least as protective as the requirements contained in Illinois Environmental Protection Agency's Illinois Urban Manual, 1995. Facilities which discharge storm water associated with construction site activities must include in their storm water pollution prevention plan procedures and requirements specified in applicable sediment and erosion site plans or storm water management plans approved by local officials. Requirements specified in sediment and erosion site plans or site permits or storm water management site plans or site permits approved by local officials that are applicable to protecting surface water resources are, upon submittal of an NOI to be authorized to discharge under this permit, incorporated by reference and are enforceable under this permit even if they are not specifically included in a storm water pollution prevention plan required under this permit. This provision does not apply to provisions of master plans, comprehensive plans, non-enforceable guidelines or technical guidance documents that are not identified in a specific plan or permit that is issued for the construction site.

(ii) Dischargers seeking alternative permit requirements are not authorized by this permit and shall submit an individual permit application in accordance with 40 CFR 122.26 at the address indicated in Part II.D (Where to Submit) of this permit, along with a description of why requirements in approved local plans or permits should not be applicable as a condition of an NPDES permit.

3. **Maintenance.** A description of procedures to maintain in good and effective operating conditions vegetation, erosion and sediment control measures and other protective measures identified in the site plan.

4. **Inspections.** Qualified personnel (provided by the permittee) shall inspect disturbed areas of the construction site that have not been finally stabilized, structural control measures, and locations where vehicles enter or exit the site at least once every seven calendar days and within 24 hours of the end of a storm that is 0.5 inches or greater or equivalent snowfall.
 - a. Disturbed areas and areas used for storage of materials that are exposed to precipitation shall be inspected for evidence of, or the potential for, pollutants entering the drainage system. Erosion and sediment control measures identified in the plan shall be observed to ensure that they are operating correctly. Where discharge locations or points are accessible, they shall be inspected to ascertain whether erosion control measures are effective in preventing significant impacts to receiving waters. Locations where vehicles enter or exit the site shall be inspected for evidence of offsite sediment tracking.
 - b. Based on the results of the inspection, the description of potential pollutant sources identified in the plan in accordance with paragraph IV.D.1 (Site Description) of this permit and pollution prevention measures identified in the plan in accordance with paragraph IV.D.2 (Controls) of this permit shall be revised as appropriate as soon as practicable after such inspection. Such modifications shall provide for timely implementation of any changes to the plan within 7 calendar days following the inspection.
 - c. A report summarizing the scope of the inspection, name(s) and qualifications of personnel making the inspection, the date(s) of the inspection, major observations relating to the implementation of the storm water pollution prevention plan, and actions taken in accordance with paragraph b above shall be made and retained as part of the storm water pollution prevention plan for at least three years after the date of inspection. The report shall be signed in accordance with Part VI.G (Signatory Requirements) of this permit.
 - d. The permittee shall complete and submit within 5 days an "Incidence of Noncompliance" (ION) report for any violation of the storm water pollution prevention plan observed during an inspection conducted, including those not required by the Plan. Submission shall be on forms provided by the Agency and include specific information on the cause of noncompliance, actions which were taken to prevent any further causes of noncompliance, and a statement detailing any environmental impact which may have resulted from the noncompliance.
 - e. All reports of noncompliance shall be signed by a responsible authority as defined in Part VI.G (Signatory Requirements).
 - f. All reports of noncompliance shall be mailed to the Agency at the following address:

Illinois Environmental Protection Agency
Division of Water Pollution Control
Compliance Assurance Section
1021 North Grand East
Post Office Box 19276
Springfield, Illinois 62794-9276

5. **Non-Storm Water Discharges** - Except for flows from fire fighting activities, sources of non-storm water listed in paragraph III.A.2 of this permit that are combined with storm water discharges associated with industrial activity must be identified in the plan. The plan shall identify and insure the implementation of appropriate pollution prevention measures for the non-storm water component(s) of the discharge.

E. Additional requirements for storm water discharge from industrial activities other than construction, including dedicated asphalt plants, and dedicated concrete plants. - This permit may only authorize a storm water discharge associated with industrial activity from a construction site that is mixed with a storm water discharge from an industrial source other than construction, where:

1. the industrial source other than construction is located on the same site as the construction activity;
2. storm water discharges associated with industrial activity from the areas of the site where construction activities are occurring are in compliance with the terms of this permit; and
3. storm water discharges associated with industrial activity from the areas of the site where industrial activity other than construction are occurring (including storm water discharges from dedicated asphalt plants (other than asphalt emulsion facilities) and dedicated concrete plants) are in compliance with the terms, including applicable NOI or application requirements, of a different NPDES general permit or individual permit authorizing such discharges.

F. Contractors.

1. The storm water pollution prevention plan must clearly identify for each measure identified in the plan, the contractor(s) or subcontractor(s) that will implement the measure. All contractors and subcontractors identified in the plan must sign a copy of the certification statement in paragraph 2 below in accordance with Part VI.G (Signatory Requirements) of this permit. All certifications must be included in the storm water pollution prevention plan except for owners that are acting as contractor.
2. **Certification Statement.** All contractors and subcontractors identified in a storm water pollution prevention plan in accordance with paragraph 1 above shall sign a copy of the following certification statement before conducting any professional service at the site identified in the storm water pollution prevention plan:

"I certify under penalty of law that I understand the terms and conditions of the general National Pollutant Discharge Elimination System (NPDES) permit (ILR100000) that authorizes the storm water discharges associated with industrial activity from the construction site identified as part of this certification."

The certification must include the name and title of the person providing the signature in accordance with Part VI.G of this permit; the name, address and telephone number of the contracting firm; the address (or other identifying description) of the site; and the date the certification is made.

Part V. RETENTION OF RECORDS

- A. The permittee shall retain copies of storm water pollution prevention plans and all reports and notices required by this permit, and records of all data used to complete the Notice of Intent to be covered by this permit, for a period of at least three years from the date that the site is finally stabilized. This period may be extended by request of the Agency at any time.
- B. The permittee shall retain a copy of the storm water pollution prevention plan required by this permit at the construction site from the date of project initiation to the date of final stabilization.

Part VI. STANDARD PERMIT CONDITIONS**A. Duty to Comply.**

1. The permittee must comply with all conditions of this permit. Any permit noncompliance constitutes a violation of Illinois Environmental Protection Act and the CWA and is grounds for enforcement action; for permit termination, revocation and reissuance, or modification; or for denial of a permit renewal application.

2. Penalties for Violations of Permit Conditions.**a. Criminal**

- (1). **Negligent Violations** The CWA provides that any person who negligently violates permit conditions implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act is subject to a fine of not less than \$2,500 nor more than \$25,000 per day of violation, or by imprisonment for not more than 1 years, or both. The Environmental Protection Act provides that any person who negligently violates subsection (f) of Section 12 of the Act, any provision of any regulation, standard, or filing requirement under subsection (b) of Section 39 of the Act, or any NPDES permit issued under the Act is subject to a fine not to exceed \$10,000 for each day of violation.
- (2). **Knowing Violations** The CWA provides that any person who knowingly violates permit conditions implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act is subject to a fine of not less than \$5,000 nor more than \$50,000 per day of violation, or by imprisonment for not more than 3 year, or both. The Environmental Protection Act provides that any person who knowingly violates subsection (f) of Section 12 of the Act, any provision of any regulation, standard, or filing requirement under subsection (b) of Section 39 of the Act, or any NPDES permit issued under the Act commits a Class 4 felony, and in addition to any other penalty prescribed by law is subject to a fine not to exceed \$25,000 for each day of violation.
- (3). **Knowing Endangerment** The CWA provides that any person who knowingly violates permit conditions implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act and who knows at that time that he is placing another person in imminent danger of death or serious bodily injury is subject to a fine of not more than \$250,000, or by imprisonment for not more than 15 years, or both.
- (4). **False Statement** The CWA provides that any person who knowingly makes any false material statement, representation, or certification in any application, record, report, plan, or other document filed or required to be maintained under the Act or who knowingly falsifies, tampers with, or renders inaccurate, any monitoring device or method required to be maintained under the Act, shall upon conviction, be punished by a fine of not more than \$10,000 or by imprisonment for not more than 2 years, or by both. If a conviction of a permittee is for a violation committed after a first conviction of such person under this paragraph, punishment shall be by a fine of not more than \$20,000 per day of violation, or by imprisonment of not more than 4 years, or by both. (See Section 309.c.4 of the Clean Water Act). The Environmental Protection Act provides that any person who knowingly makes any false statement, representation, or certification in an application form, or form pertaining to a NPDES permit or who knowingly renders inaccurate any monitoring device or record required in connection with any such permit or with any discharge which is subject to the provisions of subsection (f) of Section 12 of the Act commits a Class A misdemeanor, and in addition to any other penalties provided by law is subject to a fine not to exceed \$10,000 for each day of violation.

- b. **Civil Penalties**- The CWA provides that any person who violates a permit condition implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act is subject to a civil penalty not to exceed \$25,000 per day for each violation. The Environmental Protection Act provides that any person who violates subsection (f) of Section 12 of the Act, any provision of any regulation, standard, or filing requirement under subsection (b) of Section 39 of the Act, or any NPDES permit issued under the Act is subject to a civil penalty not to exceed \$50,000 for each violation and an additional civil penalty of not to exceed \$10,000 for each day during which the violation continues.

- c. **Administrative Penalties** - The CWA provides that any person who violates a permit condition implementing Sections 301, 302, 306, 307, 308, 318, or 405 of the Act is subject to an administrative penalty, as follows:

- (1). **Class I penalty** Not to exceed \$10,000 per violation nor shall the maximum amount exceed \$25,000.
- (2). **Class II penalty** Not to exceed \$10,000 per day for each day during which the violation continues nor shall the maximum amount exceed \$125,000.

- B. **Continuation of the Expired General Permit** This permit expires five years from the date of issuance. An expired general permit continues in force and effect until a new general permit or an individual permit is issued. Only those facilities authorized to discharge under the expiring general permit are covered by the continued permit.

- C. **Need to halt or reduce activity not a defense.** It shall not be a defense for a permittee in an enforcement action that it would have been necessary to halt or reduce the permitted activity in order to maintain compliance with the conditions of this permit.

- D. **Duty to Mitigate.** The permittee shall take all reasonable steps to minimize or prevent any discharge in violation of this permit which has a reasonable likelihood of adversely affecting human health or the environment.
- E. **Duty to Provide Information.** The permittee shall furnish within a reasonable time to the Agency or local agency approving sediment and erosion plans, grading plans, or storm water management plans; or in the case of a storm water discharge associated with industrial activity which discharges through a municipal separate storm sewer system with an NPDES permit, to the municipal operator of the system, any information which is requested to determine compliance with this permit. Upon request, the permittee shall also furnish to the Agency or local agency approving sediment and erosion plans, grading plans, or storm water management plans; or in the case of a storm water discharge associated with industrial activity which discharges through a municipal separate storm sewer system with an NPDES permit, to the municipal operator of the system, copies of records required to be kept by this permit.
- F. **Other Information.** When the permittee becomes aware that he or she failed to submit any relevant facts or submitted incorrect information in the Notice of Intent or in any other report to the Agency, he or she shall promptly submit such facts or information.
- G. **Signatory Requirements.** All Notices of Intent, storm water pollution prevention plans, reports, certifications or information either submitted to the Agency or the operator of a large or medium municipal separate storm sewer system, or that this permit requires be maintained by the permittee, shall be signed.
1. All Notices of Intent shall be signed as follows:
 - a. For a corporation: by a responsible corporate officer. For the purpose of this section, a responsible corporate officer means: (1) a president, secretary, treasurer, or vice-president of the corporation in charge of a principal business function, or any other person who performs similar policy or decision-making functions for the corporation; or (2) the manager of one or more manufacturing, production or operating facilities employing more than 250 persons or having gross annual sales or expenditures exceeding \$25,000,000 (in second-quarter 1980 dollars) if authority to sign documents has been assigned or delegated to the manager in accordance with corporate procedures;
 - b. For a partnership or sole proprietorship: by a general partner or the proprietor, respectively; or
 - c. For a municipality, State, Federal, or other public agency: by either a principal executive officer or ranking elected official. For purposes of this section, a principal executive officer of a Federal agency includes (1) the chief executive officer of the agency, or (2) a senior executive officer having responsibility for the overall operations of a principal geographic unit of the agency.
 2. All reports required by the permit and other information requested by the Agency shall be signed by a person described above or by a duly authorized representative of that person. A person is a duly authorized representative only if:
 - a. The authorization is made in writing by a person described above and submitted to the Agency.
 - b. The authorization specifies either an individual or a position having responsibility for the overall operation of the regulated facility or activity, such as the position of manager, operator, superintendent, or position of equivalent responsibility or an individual or position having overall responsibility for environmental matters for the company. (A duly authorized representative may thus be either a named individual or any individual occupying a named position).
 - c. **Changes to authorization.** If an authorization under paragraph I.C (Authorization) is no longer accurate because a different individual or position has responsibility for the overall operation of the construction site, a new authorization satisfying the requirements of paragraph I.C must be submitted to the Agency prior to or together with any reports, information, or applications to be signed by an authorized representative.
 - d. **Certification.** Any person signing documents under this Part shall make the following certification:

"I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gathered and evaluated the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations."
- H. **Penalties for Falsification of Reports.** Section 309(c)(4) of the Clean Water Act provides that any person who knowingly makes any false material statement, representation, or certification in any record or other document submitted or required to be maintained under this permit, including reports of compliance or noncompliance shall, upon conviction, be punished by a fine of not more than \$10,000, or by imprisonment for not more than 2 years, or by both. Section 44(j)(4) and (5) of the Environmental Protection Act provides that any person who knowingly makes any false statement, representation, or certification in an application form, or form pertaining to a NPDES permit commits a Class A misdemeanor, and in addition to any other penalties provided by law is subject to a fine not to exceed \$10,000 for each day of violation.
- I. **Penalties for Falsification of Monitoring Systems.** The CWA provides that any person who falsifies, tampers with, or knowingly renders inaccurate any monitoring device or method required to be maintained under this permit shall, upon conviction, be punished by fines and imprisonment described in Section 309 of the CWA. The Environmental Protection Act provides that any person who knowingly renders inaccurate any monitoring device or record required in connection with any NPDES permit or with any discharge which is subject to the provisions of subsection (f) of Section 12 of the Act commits a Class A misdemeanor, and in addition to any other penalties provided by law is subject to a fine not to exceed \$10,000 for each day of violation.
- J. **Oil and Hazardous Substance Liability.** Nothing in this permit shall be construed to preclude the institution of any legal action or relieve the permittee from any responsibilities, liabilities, or penalties to which the permittee is or may be subject under section 311 of the CWA.
- K. **Property Rights.** The issuance of this permit does not convey any property rights of any sort, nor any exclusive privileges, nor does it authorize any injury to private property nor any invasion of personal rights, nor any infringement of Federal, State or local laws or regulations.

- L. **Severability.** The provisions of this permit are severable, and if any provision of this permit, or the application of any provision of this permit to any circumstance, is held invalid, the application of such provision to other circumstances, and the remainder of this permit shall not be affected thereby.
- M. **Transfers.** This permit is not transferable to any person except after notice to the Agency. The Agency may require the discharger to apply for and obtain an individual NPDES permit as stated in Part I.C (Authorization).
- N. **Requiring an Individual Permit or an Alternative General Permit.**
1. The Agency may require any person authorized by this permit to apply for and/or obtain either an individual NPDES permit or an alternative NPDES general permit. Any interested person may petition the Agency to take action under this paragraph. Where the Agency requires a discharger authorized to discharge under this permit to apply for an individual NPDES permit, the Agency shall notify the discharger in writing that a permit application is required. This notification shall include a brief statement of the reasons for this decision, an application form, a statement setting a deadline for the discharger to file the application, and a statement that on the effective date of the individual NPDES permit or the alternative general permit as it applies to the individual permittee, coverage under this general permit shall automatically terminate. Applications shall be submitted to the Agency indicated in Part II.D (Where to Submit) of this permit. The Agency may grant additional time to submit the application upon request of the applicant. If a discharger fails to submit in a timely manner an individual NPDES permit application as required by the Agency under this paragraph, then the applicability of this permit to the individual NPDES permittee is automatically terminated at the end of the day specified by the Agency for application submittal.
 2. Any discharger authorized by this permit may request to be excluded from the coverage of this permit by applying for an individual permit. In such cases, the permittee shall submit an individual application in accordance with the requirements of 40 CFR 122.26(c)(1)(ii), with reasons supporting the request, to the Agency at the address indicated in Part II.D (Where to Submit) of this permit. The request may be granted by issuance of any individual permit or an alternative general permit if the reasons cited by the permittee are adequate to support the request.
 3. When an individual NPDES permit is issued to a discharger otherwise subject to this permit, or the discharger is authorized to discharge under an alternative NPDES general permit, the applicability of this permit to the individual NPDES permittee is automatically terminated on the effective date of the individual permit or the date of authorization of coverage under the alternative general permit, whichever the case may be. When an individual NPDES permit is denied to a discharger otherwise subject to this permit, or the discharger is denied for coverage under an alternative NPDES general permit, the applicability of this permit to the individual NPDES permittee remains in effect, unless otherwise specified by the Agency.
- O. **State/Environmental Laws.** No condition of this permit shall release the permittee from any responsibility or requirements under other environmental statutes or regulations.
- P. **Proper Operation and Maintenance.** The permittee shall at all times properly operate and maintain all facilities and systems of treatment and control (and related appurtenances) which are installed or used by the permittee to achieve compliance with the conditions of this permit and with the requirements of storm water pollution prevention plans. Proper operation and maintenance also includes adequate laboratory controls and appropriate quality assurance procedures. Proper operation and maintenance requires the operation of backup or auxiliary facilities or similar systems, installed by a permittee only when necessary to achieve compliance with the conditions of the permit.
- Q. **Inspection and Entry.** The permittee shall allow the Agency or, in the case of a construction site which discharges through a municipal separate storm sewer, an authorized representative of the municipal operator or the separate storm sewer receiving the discharge, upon the presentation of credentials and other documents as may be required by law, to:
1. Enter upon the permittee's premises where a regulated facility or activity is located or conducted or where records must be kept under the conditions of this permit;
 2. Have access to and copy at reasonable times, any records that must be kept under the conditions of this permit; and
 3. Inspect at reasonable times any facilities or equipment (including monitoring and control equipment).
- R. **Permit Actions.** This permit may be modified, revoked and reissued, or terminated for cause. The filing of a request by the permittee for a permit modification, revocation and reissuance, or termination, or a notification of planned changes or anticipated noncompliance does not stay any permit condition.

Part VII. REOPENER CLAUSE

- A. If there is evidence indicating potential or realized impacts on water quality due to any storm water discharge associated with industrial activity covered by this permit, the discharger may be required to obtain individual permit or an alternative general permit in accordance with Part I.C (Authorization) of this permit or the permit may be modified to include different limitations and/or requirements.
- B. Permit modification or revocation will be conducted according to provisions of 35 Ill. Adm. Code, Subtitle C, Chapter I and the provisions of 40 CFR 122.62, 122.63, 122.64 and 124.5.

Part VIII. DEFINITIONS

"Agency" means the Illinois Environmental Protection Agency.

"Best Management Practices" ("BMPs") means schedules of activities, prohibitions of practices, maintenance procedures, and other management practices to prevent or reduce the pollution of waters of the United States. BMPs also include treatment requirements, operating procedures, and practices to control plant site runoff, spillage or leaks, sludge or waste disposal, or drainage from raw material storage.

"Commencement of Construction" - The initial disturbance of soils associated with clearing, grading, or excavating activities or other construction activities.

"CWA" means Clean Water Act (formerly referred to as the Federal Water Pollution Control Act or Federal Water Pollution Control Act Amendments of 1972) Pub.L. 92-500, as amended Pub. L. 95-217, Pub. L. 95-576, Pub. L. (96-483 and Pub. L. 97-117, 33 U.S.C. 1251 et.seq.)

"Dedicated portable asphalt plant" - A portable asphalt plant that is located on or contiguous to a construction site and that provides asphalt only to the construction site that the plant is located on or adjacent to. The term dedicated portable asphalt plant does not include facilities that are subject to the asphalt emulsion effluent limitation guideline at 40 CFR 443.

"Dedicated portable concrete plant" - A portable concrete plant that is located on or contiguous to a construction site and that provides concrete only to the construction site that the plant is located on or adjacent to.

"Dedicated sand or gravel operation" - An operation that produces sand and/or gravel for a single construction project.

"Director" means the Director of the Illinois Environmental Protection Agency or an authorized representative.

"Final Stabilization" means that all soil disturbing activities at the site have been completed, and that a uniform perennial vegetative cover with a density of 70% the cover for unpaved areas and areas not covered by permanent structures has been established or equivalent stabilization measures (such as the use of riprap, gabions or geotextiles) have been employed.

"Large and Medium municipal separate storm sewer system" means all municipal separate storm sewers that are either:

- (i) located in an incorporated place (city) with a population of 100,000 or more as determined by the latest Decennial Census by the Bureau of Census (these cities are listed in Appendices F and G of 40 CFR Part 122); or
- (ii) located in the counties with unincorporated urbanized populations of 100,000 or more, except municipal separate storm sewers that are located in the incorporated places, townships or towns within such counties (these counties are listed in Appendices H and I of 40 CFR Part 122); or
- (iii) owned or operated by a municipality other than those described in paragraph (i) or (ii) and that are designated by the Director as part of the large or medium municipal separate storm sewer system.

"NOI" means notice of intent to be covered by this permit (see Part II of this permit.)

"Point Source" means any discernible, confined, and discrete conveyance, including but not limited to, any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation, landfill leachate collection system, vessel or other floating craft from which pollutants are or may be discharges. This term does not include return flows from irrigated agriculture or agricultural storm water runoff.

"Runoff coefficient" means the fraction of total rainfall that will appear at the conveyance as runoff.

"Storm Water" means storm water runoff, snow melt runoff, and surface runoff and drainage.

"Storm Water Associated with Industrial Activity" means the discharge from any conveyance which is used for collecting and conveying storm water and which is directly related to manufacturing, processing or raw materials storage areas at an industrial plant. The term does not include discharges from facilities or activities excluded from the NPDES program. For the categories of industries identified in subparagraphs (i) through (x) of this subsection, the term includes, but is not limited to, storm water discharges from industrial plant yards; immediate access roads and rail lines used or traveled by carriers of raw materials, manufactured products, waste material, or by-products used or created by the facility; material handling sites; refuse sites; sites used for the application or disposal of process waste waters (as defined at 40 CFR 401); sites used for the storage and maintenance of material handling equipment; sites used for residual treatment, storage, or disposal; shipping and receiving areas; manufacturing buildings; storage areas (including tank farms) for raw materials, and intermediate and finished products; and areas where industrial activity has taken place in the past and significant materials remain and are exposed to storm water. For the categories of industries identified in subparagraph (xi), the term includes only storm water discharges from all areas listed in the previous sentence (except access roads) where material handling equipment or activities, raw materials, intermediate products, final products, waste materials, by-products, or industrial machinery are exposed to storm water. For the purposes of this paragraph, material handling activities include the: storage, loading and unloading, transportation, or conveyance of any raw material, intermediate product, finished product, by-product or waste product. The term excludes areas located on plant lands separate from the plant's industrial activities, such as office buildings and accompanying parking lots as long as the drainage from the excluded areas is not mixed with storm water drained from the above described areas. Industrial facilities (including industrial facilities that are Federally or municipally owned or operated that meet the description of the facilities listed in this paragraph (i)- (xi)) include those facilities designated under 40 CFR 122.26(a)(1)(v). The following categories of facilities are considered to be engaging in "industrial activity" for purposes of this subsection:

- (i) Facilities subject to storm water effluent limitations guidelines, new source performance standards, or toxic pollutant effluent standards under 40 CFR Subchapter N (except facilities with toxic pollutant effluent standards which are exempted under category (xi) of this paragraph);
- (ii) Facilities classified as Standard Industrial Classifications 24 (except 2434), 26 (except 265 and 267), 28, 29, 311, 32, 33, 3441, 373;
- (iii) Facilities classified as Standard Industrial Classifications 10 through 14 (mineral industry) including active or inactive mining operations (except for areas of coal mining operations meeting the definition of a reclamation area under 40 CFR 434.11(l)) and oil and gas exploration, production, processing, or treatment operations, or transmission facilities that discharge storm water contaminated by contact with or that has come into contact with, any overburden, raw material, intermediate products, finished products, byproducts or waste products located on the site of such operations; inactive mining operations are mining sites that are not being actively mined, but which have an identifiable owner/operator;
- (iv) Hazardous waste treatment, storage, or disposal facilities, including those that are operating under interim status or a permit under Subtitle C of

RCRA;

- (v) Landfills, land application sites, and open dumps that have received any industrial wastes (waste that is received from any of the facilities described under this subsection) including those that are subject to regulation under Subtitle D of RCRA;
- (vi) Facilities involved in the recycling of materials, including metal scrapyards, battery reclaimers, salvage yards, and automobile junkyards, including but limited to those classified as Standard Industrial Classification 5015 and 5093;
- (vii) Steam electric power generating facilities, including coal handling sites;
- (viii) Transportation facilities classified as Standard Industrial Classifications 40, 41, 42, 44, and 45 which have vehicle maintenance shops, equipment cleaning operations, or airport deicing operations. Only those portions of the facility that are either involved in vehicle maintenance (including vehicle rehabilitation, mechanical repairs, painting, fueling, and lubrication), equipment cleaning operations, airport deicing operations, or which are otherwise identified under subparagraphs (i)-(vii) or (ix)-(xi) of this subsection are associated with industrial activity;
- (ix) Treatment works treating domestic sewage or any other sewage sludge or wastewater treatment device or system, used in the storage treatment, recycling, and reclamation of municipal or domestic sewage, including land dedicated to the disposal of sewage sludge that are located within the confines of the facility, with a design flow of 1.0 mgd or more, or required to have an approved pretreatment program under 40 CFR 403. Not included are farm lands, domestic gardens or lands used for sludge management where sludge is beneficially reused and which are not physically located in the confines of the facility, or areas that are in compliance with 40 CFR 503;
- (x) Construction activity including clearing, grading and excavation activities except: operations that result in the disturbance of less than five acres of total land area which are not part of a larger common plan of development or sale;
- (xi) Facilities under Standard Industrial Classifications 20, 21, 22, 23, 2434, 25, 265, 267, 27, 283, 31 (except 311), 34 (except 3441), 35, 36, 37 (except 373), 38, 39, 4221-25, (and which are not otherwise included within categories (i)-(x)).

"Waters" mean all accumulations of water, surface and underground, natural, and artificial, public and private, or parts thereof, which are wholly or partially within, flow through, or border upon the State of Illinois, except that sewers and treatment works are not included except as specially mentioned; provided, that nothing herein contained shall authorize the use of natural or otherwise protected waters as sewers or treatment works except that in-stream aeration under Agency permit is allowable.

APPENDIX B - SOIL QUALITY - URBAN TECHNICAL NOTES

INTRODUCTION

These technical notes provide information about soil quality-related resource issues tailored for the urban environment. They are intended for use by government employees, homeowners, builders, consultants, developers, and others interested in natural resource conservation.

Urban Technical Note No. #1 provides background information on erosion sedimentation on construction sites. It describes impacts on the soil's ability to perform important functions and suggests management practices for preventing or mitigating soil quality degradation in the urban environment.

Urban Technical Note No. #2 provides background information on urban soil compaction, describes impact of soil compaction on the soil's ability to perform important functions, and suggests management practices for preventing or mitigating soil quality degradation in the urban environment.

Urban Technical Note No. #3 provides background information on heavy metal contamination in soils, along with management practices for preventing or mitigating soil quality degradation in the urban environment.

This section was revised in October 2001.

Urban Technical
Note No. 1

March, 2000

This is the first note in a series of Soil Quality-Urban technical notes on the effects of land management on soil quality.

Introduction

Soil is a crucial component of rural and urban environments, and in both places land management is the key to soil quality. This series of technical notes examines the urban activities causing soil degradation and sedimentation, and the management practices that protect the functions that urban societies demand from soil. This technical note will focus on soil erosion and sedimentation from construction sites.

Off site damage from sediment is the most critical problem facing construction sites. Erosion, which produces this sediment, is accelerated when soil is disturbed, left bare, and exposed to the abrasive action of wind and water. Unless adequate measures are taken to prevent this abnormal, highly accelerated soil removal, it becomes the most visible and damaging factor in the deterioration of soil quality and the environmental quality of urban areas.

Construction Erosion

Although erosion on construction sites often affects only a relatively small acreage of land in a watershed, it is a major source of sediment because the potential for erosion on highly disturbed land is commonly 100 times greater than on agricultural land (Brady and Weil, 1999). Erosion and sediment damages occur both on and off the construction site, and all of society pays for the destructive impacts.

Erosion Impacts

Construction activities, such as grading and filling, drastically reduce soil quality on construction sites. Left unprotected, sites will be further degraded by erosion and begin to adversely affect the surrounding environment. The goal of soil quality management on construction sites is to revegetate for protection against off-site damage and increase soil organic matter levels to remedy the on-site damage caused by site preparation.

On-site impacts: The loss of topsoil, either by actual removal with heavy equipment or erosion by wind and water, is the worst on-site damage in urban areas. This layer of soil has the highest biological activity, organic matter, and plant nutrients—all key components of healthy soil. The on-site loss of this upper layer of soil nearly eliminates the soil's natural ability to provide nutrients, regulate water flow, and combat pests and disease.

- Loss of nutrients and nutrient holding capacity, results in a less fertile environment for lawns and landscape plants. The organic matter and finer soil particles are responsible for soil fertility and are washed away first, leaving larger, less reactive particles such as sand and gravel.
- As organic matter is lost, soil density increases and compaction occurs. Compaction lowers the infiltration rate of water and reduces the available water holding capacity. This results in poorer growth of lawns, gardens, flowerbeds, shrubs, and trees, as well as making the site more susceptible to drought and requiring more frequent watering. Additionally, soil amendments such as fertilizer and pesticides cannot move into the soil and, instead, run off into nearby lakes and streams. Lower organic matter levels are also associated with weaker soil aggregates and therefore greater risk of further erosion and soil crusting.
- The surface organic matter is also the food source and habitat for beneficial microorganisms and insects. The loss of this material drastically reduces the soils natural ability to control disease and pest outbreaks, increasing the need for pesticides. These microorganisms are also key to removing or buffering toxic elements or contaminants.

Off-site impacts: Erosion from construction sites has off-site environmental and economic impacts. Erosion creates two major water quality problems in surface waters and drainage ways: excess nutrients and excess sediment. These problems adversely impact the health and biological diversity of water bodies. More specifically:

- Excess nutrients impact water quality through eutrophication, a process whereby excess nitrogen and phosphorus causes unwanted biological growth.
- Sediment reduces water quality by making the water turbid (cloudy). Turbidity prevents sunlight from penetrating the water and thus reduces photosynthesis and underwater vegetation. Oxygen levels are reduced in turbid waters, further degrading habitat for fish and other aquatic organisms.
- Sediment can build up in stream channels, lowering flow capacity. The problem of low stream capacity is compounded as runoff increases from newly built-up or paved areas and causes stream channels to receive larger amounts of water in shorter periods of time. This leads to more frequent flooding in areas that never or only rarely flooded in the past. In flood-prone areas, levees may need to be built or enlarged to better protect public safety.
- A financial burden results from clean up of sediment-damaged areas. Taxpayers often bear the cost of removing sediment from public roads, road ditches, culverts or streams; not to mention damage to homes and the safety hazards associated with flooding. Other costs of erosion that are borne by the public are degraded soils, a polluted environment, more runoff, greater need for irrigation, and aesthetically displeasing sites.

Many local governments enforce regulations to control or prevent erosion from construction sites. State and local laws and the Clean Water Act of 1992 can require contractors to develop detailed erosion and sediment control plans before beginning construction projects over approximately 2.5 acres.

Tool for Estimating Erosion on Construction Sites

Soil loss from sheet and rill erosion on construction sites, mined lands, reclaimed lands, and other highly disturbed areas can be estimated using the Revised Universal Soil Loss Equation (RUSLE) version 1.06. A handbook is available to help the user estimate factor values and apply the computer model (Toy and Foster, 1998).

The person in each NRCS State or Basin Area Office with responsibility for RUSLE (typically the state agronomist) should be contacted for assistance with estimating soil loss on construction sites using RUSLE.

Evaluating Management Practices and Developing Alternative Systems

Erosion control practices and management systems can be evaluated and planned using the RUSLE model. The erosion control

benefits of cover and management practices such as adding mulch, seeding, and sod can be estimated with the RUSLE conservation management (C) factor. Structural and vegetative practices such as straw bales, silt fences, gravel bags, narrow grass strips or buffers, vegetative barriers, terraces and diversions can be evaluated with the RUSLE conservation practice (P) factor.

Alternative management systems, consisting of combinations of cover and structural practices, can be developed with the RUSLE program. Ideally, these management systems will reduce or control erosion and sedimentation and improve soil quality. Each site and management system must be evaluated individually, since erosion estimates will vary depending on climate, soils, topography, and cover conditions.

The RUSLE model also estimates the amount of sediment delivered to the base of a slope (sediment yield) using the RUSLE P factor. Some temporary practices used on construction sites such as a silt fence placed at the base of the slope will not reduce erosion on the slope but will trap some of the sediment leaving that slope. The RUSLE model estimates this sediment yield, as displayed in Table 1.

Table 1. Effects of management practices on controlling erosion on a road bank. Estimated sheet and rill erosion and sediment yield using RUSLE during a construction year in Nashville, TN¹.

Site Conditions ²		Soil Loss from Road Bank (t/a/y)	Sediment Yield at Base of Slope (t/a/y)
-1 st 6 mo	2 nd 6 mo		
Bare	Bare	400	400
Bare	Bare, Silt Fence	400	250
Bare	Mulch, Seeded	140	140
Bare	Sod, Diversion	40	5

¹Effects of management will vary under other climatic conditions. For example, soil loss and sediment yield will be 35 % and 80 % less in Chicago and Denver, respectively, than values shown in table.

²Roadside cutbank, 100 ft. long at 30% gradient. Site disturbed from March – June. Soil loss and sediment yield during a single construction season. Soil is a silt loam. Silt fence placed at base of slope. Diversion placed in middle of slope.

Principles of Construction Erosion Control

Prevention of urban erosion is best. Here are some basic principles of erosion control on construction sites (adapted from Brady and Weil, 1999):

1. Divide the project into smaller phases clearing smaller areas of vegetation.
2. Schedule excavation during low-rainfall periods, when possible.
3. Fit development to the terrain.
4. Excavate immediately before construction instead of leaving soils exposed for months or years.
5. Cover disturbed soils as soon as possible with vegetation or other materials (mulch) to reduce erosion potential.
6. Divert water from disturbed areas.
7. Control concentrated flow and runoff to reduce the volume and velocity of water from work sites to prevent formation of rills and gullies.
8. Minimize length and steepness of slopes (e.g. use bench terraces).
9. Prevent sediment movement off-site.
10. Inspect and maintain any structural control measures.
11. Where wind erosion is a concern, plan and install windbreaks.
12. Avoid soil compaction by restricting the use of trucks and heavy equipment to limited areas.
13. Soils compacted by grading need to be broken up or tilled prior to vegetating or placing sod.

It is inevitable that soil will be exposed during construction. However, it is essential that the exposed land is minimized, and cover is established as quickly as possible. Conservation practices that provide immediate permanent cover (sod) or provide intermittent cover (mulches and permanent seeding) drastically reduce soil losses and runoff (Table 2). Other supporting practices such as diversions or terraces change slope

lengths, thus reducing runoff and erosion. These supporting practices provide temporary protection for vegetation or sod until they become established and provide permanent protection for the site. There are other conservation practices available for construction and urban erosion (NRCS Watershed Science Institute, 2000).

Table 2. Effectiveness of various groundcovers in reducing runoff and soil erosion for a single simulated rain event (3.78 in/h) at University of Maryland’s turf grass research facility¹ (adapted from Brady and Weil, 1999).

Material	Soil loss ² (tons/acre)	% of Rainfall Runoff	% Ground Cover Established ³
Bare soil with partial cover	2.97	83	50
Woven mesh	0.18	68	61
Wood shavens in non-woven polyester netting	0.36	74	69
Coconut fiber mat	0.48	76	58
Straw (2 t/a)	0.26	60	76
Grass sod	0.04	28	NA

¹Effectiveness will vary at other locations because of differences in climate, soils and topography.

²Soil from Sassafras loamy sand with a 8 % slope and a Matapeake sandy clay loam with a 15% slope.

³Percent vegetation cover established one year after Kentucky 31 fescue grass was seeded and covered by various material.

Conclusion

Soil is important but is often an overlooked component of our urban infrastructure. It is especially important in regulating runoff of storm water and in supporting trees, shrubs, lawns, and gardens. Soil erosion during construction is often a serious problem. Many erosion control practices are available in local soil and water conservation district offices. However, the effects of erosion on construction sites continue to menace society both from on-site and off-site damages. Preventing soil-related problems before they occur is easier and more cost effective than correcting them later. Communities need to work with developers, contractors, and local governments to limit compaction and soil loss during construction operations. The result is a soil functioning properly in the urban landscape.

Urban Technical
Note No. 2

March, 2000

This is the second note
in a series of Soil
Quality-Urban technical
notes on the effects of
land management on
soil quality.

Introduction

Soil is a crucial component of rural and urban environments, and in both places land management is the key to soil quality. This series of technical notes examines the urban activities that cause soil degradation, and the management practices that protect the functions urban societies demand from soil. This technical note will focus on urban soil compaction.

Healthy soil includes not only the physical particles making up the soil, but also adequate pore space between the particles for the movement and storage of air and water. This is necessary for plant growth, and for a favorable environment for soil organisms to live. Compaction occurs when soil particles are pressed together, thereby reducing the amount of pore space. Examples of compaction in urban settings are traffic pans resulting from repeated trips across lots with trucks and machinery and excessive trampling by people, bicycles, etc. Soils are particularly susceptible to compaction if these activities occur when the soil is wet. The primary impacts of soil compaction are changes in the soil's physical properties (Schuler et al., 2000):

- Strength increases with compaction. Soil strength is the ability to resist penetration by an applied force and is desirable under roads and buildings.

- Bulk density increases with compaction. Bulk density is the weight of soil per volume. It is commonly reported as grams of oven dry soil per cubic centimeter.
- Porosity decreases with compaction. Porosity is the ratio of the volume of pores to the bulk volume of the soil.
- With compaction, the distribution of pores shifts toward smaller pore sizes. Pore size distribution is the array of pores, from very small to large, making up the soil's overall porosity.

These changes influence the movement of air and water in the soil, ease of root growth, and the biological diversity and activity in the soil. For proper plant growth, void space must be available for air and water movement.

Typically a medium textured soil has about 50 % solids and 50 % pore or void space. Compaction increases bulk density and reduces the number of large pores in the soil. (Schuler et al., 2000).

Compared to agricultural land, compaction in urban areas can be more permanent because of the difficulty in bringing in equipment to loosen the soil, due to the presence of utilities and the prevalence of perennial vegetation.

Causes of Soil Compaction in Urban Areas

Causes of compaction in urban areas are generally of two types:

1. Deliberate compaction during construction activities.
 - Compacting of entire areas in order to increase strength for paving and housing foundations without consideration for leaving non-constructed areas (landscaping areas and lawns) in a more natural state.
 - Use of heavy equipment for reshaping and sloping banks along roads and hillsides.
 - Grading lots and placing sod on hard soil or soil denuded of topsoil.
2. Unintentional compaction of the soil after construction is completed.
 - Allowing uncontrolled traffic (both vehicles and foot traffic)
 - Allowing vehicles on lawn areas around homes or businesses, especially when the soil is wet.

Impacts of Soil Compaction

For individual homeowners and businesses, soil compaction makes it difficult to establish and maintain lawns and landscaping due to:

- Restricted root growth.
- Reduced plant uptake of water and nutrients.
- Reduced available water capacity.

- Reduced soil biological activity.

For communities, excessive levels of soil compaction lead to environmental problems due to:

- Increased storm water runoff as a result of low infiltration rates of compacted soils.
- Increased flooding due to runoff.
- Increased erosion from construction sites.
- Increased water pollution potential, especially nitrates and phosphorus, in local rivers, streams, lakes, and ponds.

Detection of Soil Compaction

Generally compaction is a problem within the top 12 inches of the soil surface.

Detection of compaction can be by:

- Observing discolored or poor plant growth.
- Probing with a firm wire (survey flag) or welding rod (18" in length) into the compacted area.
- Digging down to plant roots and finding lateral root growth with little if any penetration of compacted layers.
- Taking bulk density samples (Table 2).
- Using commercially available cone penetrometers that indicate force required to penetrate the soil in terms of pressure (pounds per square inch). Roots are unable to penetrate soil compacted to 300 psi or more. This varies with soil type and moisture content of the soil when tested (Schuler et al., 2000).

Table 2. General relationship of soil bulk density to root growth based on soil texture (NRCS Soil Quality Institute, 1999).

Soil texture	Ideal bulk densities (g/cm ³)	Bulk densities that may affect root growth (g/cm ³)	Bulk densities that restrict root growth (g/cm ³)
Sands, loamy sands	<1.60	1.69	>1.80
Sandy loams, loams	<1.40	1.63	>1.80
Sandy clay loams, loams, clay loams	<1.40	1.60	>1.75
Silts, silt loams	<1.30	1.60	>1.75
Silt loams, silty clay loams	<1.10	1.55	>1.65
Sandy clays, silty clays, some clay loams (35-45% clay)	<1.10	1.49	>1.58
Clays (>45% clay)	<1.10	1.39	>1.47

Prevention of Urban Soil Compaction

Compaction problems during urban development can be avoided by proper planning. Working with local governments may help prevent total compaction in development areas. Divide large areas into sections to be consciously compacted for roads and foundations, and sections for lawns and landscaping. Disturb only areas needed for construction. Also, only manipulate soil when dry (less than field capacity).

Soil that will support lawns can be protected by subsoiling, and by stockpiling topsoil that will be returned to the site after construction. These two measures can restore water flow functions to near natural conditions. Establishing sod or seeding a lawn is much more successful on a loose soil with topsoil than on a compacted soil without adequate topsoil.

In parks and recreation areas, specific areas can be designated for heavy traffic (paved areas or trails). The remaining vegetated areas will benefit from less compaction because of controlled traffic. During special events, lay down metal or wood mats for better distribution of weight for vehicular

traffic or involving high volume of people in concentrated areas. Mesh elements have been used for sporting fields (Beard and Sifers, 1990).

These measures may take a little more time initially, but will pay dividends in the long run. The benefits of planning and wise urban development are:

- Satisfied buyers of homes with soils that function well
- Soils that have good infiltration rates (less frequent irrigation)
- Reduced run-off (less chemical and fertilizer loss to water bodies)
- Lower mortality rates of perennial vegetation (lawns and trees)
- Better plant growth and quality for shrubs, flowers, trees, gardens, and lawns.

Management Practices for Compacted Urban Soil

Although prevention is more effective, the detrimental effects of compaction can be lessened after soils are compacted. Management practices to reduce the effects of urban compaction are:

- Subsoiling to alleviate compacted soils. Always have underground utilities and other underground plumbing or wires located and marked.
- Partial or total soil replacement. Replace dense soil with loose soil or haul in topsoil.
- Increasing organic matter. In gardens, go to residue management/no-till systems and/or cover crops.
- Use of mulch, compost, manures, and amendments.
- Annual aeration of turf grasses to improve infiltration.
- Aeration of soil using a metal tube and air compressor. This is usually used around tree roots. (Personal communication with John Lesenger. Used at the Alabama Shakespeare Festival.)
- Irrigation management. Frequent, low rates of water are necessary because compacted soil holds little water. Over-irrigation wastes water and may lead to environmental pollution from lawn chemicals, nutrients, and sediment.
- Cutting grass at higher heights, which reduces evapotranspiration losses (see local turf grass recommendations—Extension Service).

Summary

Compaction changes important physical properties of the soil. Soils with higher strength, higher bulk densities, and decreased pore space have lower infiltration rates, reduced water holding capacity, and more runoff. This degradation of soil quality results in the need for more irrigation, less

healthy plants, higher plant mortality rates, and higher pollution potential from storm water runoff. Urban soil compaction is more complicated than in an agricultural setting. It is less convenient to alleviate urban compaction because soil cannot be disturbed easily around perennial vegetation, underground utilities, buildings, drive ways, etc. Planning will prevent many problems with compaction in developments and subdivisions. Preventive practices, including limiting the extent of disturbed areas, manipulating soil only when dry and restricting traffic, are more effective and less expensive than practices to alleviate compaction after it occurs. Preventing and managing compaction results in soils that function well and that benefit all of society.

Urban Technical
Note No. 3

September, 2000

This is the third note in a series of Soil Quality-Urban technical notes on the effects of land management on soil quality.

Introduction

Soil is a crucial component of rural and urban environments, and in both places land management is the key to soil quality. This series of technical notes examines the urban activities that cause soil degradation, and the management practices that protect the functions urban societies demand from soil. This technical note focuses on heavy metal soil contamination.

Metals in Soil

Mining, manufacturing, and the use of synthetic products (e.g. pesticides, paints, batteries, industrial waste, and land application of industrial or domestic sludge) can result in heavy metal contamination of urban and agricultural soils. Heavy metals also occur naturally, but rarely at toxic levels. Potentially contaminated soils may occur at old landfill sites (particularly those that accepted industrial wastes), old orchards that used insecticides containing arsenic as an active ingredient, fields that had past applications of waste water or municipal sludge, areas in or around mining waste piles and tailings, industrial areas where chemicals may have been dumped on the ground, or in areas downwind from industrial sites.

Excess heavy metal accumulation in soils is toxic to humans and other animals. Exposure to heavy metals is normally chronic (exposure over a longer period of time), due to food chain transfer. Acute (immediate) poisoning from heavy metals is rare through ingestion or dermal contact, but is possible. Chronic problems associated with long-term heavy metal exposures are:

- Lead – mental lapse.
- Cadmium – affects kidney, liver, and GI tract.
- Arsenic – skin poisoning, affects kidneys and central nervous system.

The most common problem causing *cationic* metals (metallic elements whose forms in soil are positively charged cations e.g., Pb^{2+}) are mercury, cadmium, lead, nickel, copper, zinc, chromium, and manganese. The most common anionic compounds (elements whose forms in soil are combined with oxygen and are negatively charged e.g., MoO_4^{2-}) are arsenic, molybdenum, selenium, and boron.

Prevention of Heavy Metal Contamination

Preventing heavy metal pollution is critical because cleaning contaminated soils is extremely expensive and difficult. Applicators of industrial waste or sludge must abide by the regulatory limits set by the U.S. Environmental Protection Agency (EPA) in Table 1.

Table 1. Regulatory limits on heavy metals applied to soils (Adapted from U.S. EPA, 1993).

Heavy metal	Maximum concentration in sludge (mg/kg or ppm)	Annual pollutant loading rates		Cumulative pollutant loading rates	
		(kg/ha/yr)	(lb/A/yr)	(kg/ha)	(lb/A)
Arsenic	75	2	1.8	41	36.6
Cadmium	85	1.9	1.7	39	34.8
Chromium	3000	150	134	3000	2,679
Copper	4300	75	67	1500	1,340
Lead	420	21	14	420	375
Mercury	840	15	13.4	300	268
Molybdenum	57	0.85	0.80	17	15
Nickel	75	0.90	0.80	18	16
Selenium	100	5	4	100	89
Zinc	7500	140	125	2800	2500

Prevention is the best method to protect the environment from contamination by heavy metals. With the above table, a simple equation is used to show the maximum amount of sludge that can be applied. For example, suppose city officials want to apply the maximum amount of sludge (kg/ha) on some agricultural land. The annual pollutant-loading rate for zinc is 140 kg/ha/yr (from Table 1). The lab analysis of the sludge shows a zinc concentration of 7500 mg/kg (mg/kg is the same as parts per million). How much can the applicator apply (tons/A) without exceeding the 140 kg/ha/yr?

Solution:

(1) Convert mg to kg (1,000,000 mg = 1kg) so all units are the same:

$$7500 \text{ mg} \times (1 \text{ kg}/1,000,000 \text{ mg}) = 0.0075 \text{ kg}$$

(2) Divide the amount of zinc that can be applied by the concentration of zinc in the sludge:

$$(140 \text{ kg Zn/ha}) / (0.0075 \text{ kg Zn/kg sludge}) = 18,667 \text{ kg sludge/ha}$$

(3) Convert to lb/A: $18,667 \text{ kg/ha} \times 0.893 = 16,669 \text{ lbs/A}$

$$\text{Convert lbs to tons: } 16,669 \text{ lb/A} / 2,000 \text{ lb/T} = 8.3 \text{ T sludge per acre}$$

Traditional Remediation of Contaminated Soil

Once metals are introduced and contaminate the environment, they will remain. Metals do not degrade like carbon-based (organic) molecules. The only exceptions are mercury and selenium, which can be transformed and volatilized by microorganisms. However, in general it is very difficult to eliminate metals from the environment.

Traditional treatments for metal contamination in soils are expensive and cost prohibitive when large areas of soil are contaminated. Treatments can be done *in situ* (on-site), or *ex situ* (removed and treated off-site). Both are extremely expensive. Some treatments that are available include:

1. High temperature treatments (produce a vitrified, granular, non-leachable material).
2. Solidifying agents (produce cement-like material).
3. Washing process (leaches out contaminants).

Management of Contaminated Soil

Soil and crop management methods can help prevent uptake of pollutants by plants, leaving them in the soil. The soil becomes the sink, breaking the soil-plant-animal or human cycle through which the toxin exerts its toxic effects (Brady and Weil, 1999).

The following management practices will not remove the heavy metal contaminants, but will help to immobilize them in the soil and reduce the potential for adverse effects from the metals – Note that the kind of metal (cation or anion) must be considered:

1. Increasing the soil pH to 6.5 or higher.

Cationic metals are more soluble at lower pH levels, so increasing the pH makes them less available to plants and therefore less likely to be incorporated in their tissues and ingested by humans. Raising pH has the opposite effect on anionic elements.

2. Draining wet soils.

Drainage improves soil aeration and will allow metals to oxidize, making them less soluble. Therefore when aerated, these metals are less available. The opposite is true for chromium, which is more available in oxidized forms. Active organic matter is effective in reducing the availability of chromium.

3. Applying phosphate.

Heavy phosphate applications reduce the availability of cationic metals, but have the opposite effect on anionic compounds like arsenic. Care should be taken with phosphorus applications because high levels of phosphorus in the soil can result in water pollution.

4. Carefully selecting plants for use on metal-contaminated soils

Plants translocate larger quantities of metals to their leaves than to their fruits or seeds. The greatest risk of food chain contamination is in leafy vegetables like lettuce or spinach. Another hazard is forage eaten by livestock.

Plants for Environmental Cleanup

Research has demonstrated that plants are effective in cleaning up contaminated soil (Wenzel et al., 1999). Phytoremediation is a general term for using plants to remove, degrade, or contain soil pollutants such as heavy metals, pesticides, solvents, crude oil, polyaromatic hydrocarbons, and landfill leachates. For example, prairie grasses can stimulate breakdown of petroleum products. Wildflowers were recently used to degrade hydrocarbons from an oil spill in Kuwait. Hybrid poplars can remove ammunition compounds such as TNT as well as high nitrates and pesticides (Brady and Weil, 1999).

Plants for Treating Metal Contaminated Soils

Plants have been used to stabilize or remove metals from soil and water. The three mechanisms used are *phytoextraction*, *rhizofiltration*, and *phytostabilization*. This technical note will define rhizofiltration and phytostabilization but will focus on phytoextraction.

Rhizofiltration is the adsorption onto plant roots or absorption into plant roots of contaminants that are in solution surrounding the root zone (rhizosphere). Rhizofiltration is used to decontaminate groundwater. Plants are grown in greenhouses in water instead of soil. Contaminated water from the site is used to acclimate the plants to the environment. The plants are then planted on the site of contaminated ground water where the roots take up the water and contaminants. Once the roots are saturated with the contaminant, the plants are harvested including the roots. In Chernobyl, Ukraine, sunflowers were used in this way to remove radioactive contaminants from groundwater (EPA, 1998).

Phytostabilization is the use of perennial, non-harvested plants to stabilize or immobilize contaminants in the soil and groundwater. Metals are absorbed and accumulated by roots, adsorbed onto roots, or precipitated within the rhizosphere. Metal-tolerant plants can be used to restore vegetation where natural vegetation is lacking, thus reducing the risk of water and wind erosion and leaching. Phytostabilization reduces the mobility of the contaminant and prevents further movement of the contaminant into groundwater or the air and reduces the bioavailability for entry into the food chain.

Phytoextraction

Phytoextraction is the process of growing plants in metal contaminated soil. Plant roots then translocate the metals into aboveground portions of the plant. After plants have grown for some time, they are harvested and incinerated or composted to recycle the metals. Several crop growth cycles may be needed to decrease

contaminant levels to allowable limits. If the plants are incinerated, the ash must be disposed of in a hazardous waste landfill, but the volume of the ash is much smaller than the volume of contaminated soil if dug out and removed for treatment. (See box.)

Example of Disposal

Excavating and landfilling a 10-acre contaminated site to a depth of 1 foot requires handling roughly 20,000 tons of soil. Phytoextraction of the same site would result in the need to handle about 500 tons of biomass, which is about 1/40 of the mass of the contaminated soil. In this example, if we assume the soil was contaminated with a lead concentration of 400 ppm, six to eight crops would be needed, growing four crops per season (Phytotech, 2000).

Phytoextraction is done with plants called hyperaccumulators, which absorb unusually large amounts of metals in comparison to other plants.

Hyperaccumulators contain more than 1,000 milligrams per kilogram of cobalt, copper, chromium, lead, or nickel; or 10,000 milligrams per kilogram (1 %) of manganese or zinc in dry matter (Baker and Brooks, 1989). One or more of these plant types are planted at a particular site based on the kinds of metals present and site conditions. Tables 2 and 3 demonstrate the importance of using hyperaccumulators.

Table 2. Percentage decrease in water-extractable zinc and cadmium in three soils after growth of Alpine pennycress (*Thlaspi caerulescens*) (McGrath, 1998).

Site Sampled	Zn	Cd
Farm	28	10
Garden	17	22
Mountain	64	70

Table 3. Removal of zinc in a hypothetical 4.5 T/A (dry matter) crop growing in soil contaminated with 1000 (ppm) zinc with a target of 50 ppm, showing the importance of hyperaccumulation (>10,000 ppm zinc) (McGrath, 1998).

ppm Zn in plant	Lbs. of Zn removed	% of soil total in one crop	years to target
100	0.9	0.04	2470.0
1000	9	0.38	247.0
10,000	90	3.85	24.7
20,000	179	7.69	12.4
30,000	268	11.54	8.2

Phytoextraction is easiest with metals such as nickel, zinc, and copper because these metals are preferred by a majority of the 400 hyperaccumulator plants. Several plants in the genus *Thlaspi* (pennycress) have been known to take up more than 30,000 ppm (3%) of zinc in their tissues. These plants can be used as ore because of the high metal concentration (Brady and Weil, 1999).

Of all the metals, lead is the most common soil contaminant (EPA, 1993). Unfortunately, plants do not accumulate lead under natural conditions. A chelator such as EDTA (ethylenediaminetetraacetic acid) has to be added to the soil as an amendment. The EDTA makes the lead available to the plant. The most common plant used for lead extraction is Indian mustard (*Brassica juncea*). Phytotech (a private research company) has reported that they have cleaned up lead-contaminated sites in New Jersey to below the industrial standards in 1 to 2 summers using Indian mustard (Watanabe, 1997).

Plants are available to remove zinc, cadmium, lead, selenium, and nickel from soils at rates that are medium to long-term, but rapid enough to be useful. Many of the plants that hyperaccumulate metals produce low biomass, and need to be bred for much higher biomass production.

Current genetic engineering efforts at USDA in Beltsville, MD, are aimed toward developing pennycress (*Thlaspi*) that is extremely zinc tolerant. These taller-than-normal plants would have more biomass, thereby taking up larger quantities of contaminating metals (Watanabe, 1997).

Traditional cleanup *in situ* may cost between \$10.00 and \$100.00 per cubic meter (m^3), whereas removal of contaminated material (*ex situ*) may cost as high \$30.00 to \$300/ m^3 . In comparison, phytoremediation may only cost \$0.05/ m^3 (Watanabe, 1997).

Future Prospects

Phytoremediation has been studied extensively in research and small-scale demonstrations, but in only a few full-scale applications. Phytoremediation is moving into the realm of commercialization (Watanabe, 1997). It is predicted that the phytoremediation market will reach \$214 to \$370 million by the year 2005 (Environmental Science & Technology, 1998).

Given the current effectiveness, phytoremediation is best suited for cleanup over a wide area in which contaminants are present at low to medium concentrations. Before phytoremediation is fully commercialized, further research is needed to assure that tissues of plants used for phytoremediation do not have adverse environmental effects if eaten by wildlife or used by humans for things such as mulch or firewood (EPA, 1998). Research is also needed to find more efficient bioaccumulators, hyperaccumulators that produce more biomass, and to further monitor current field trials to ensure a thorough understanding. There is the need for a commercialized smelting method to extract the metals from plant biomass so they can be recycled.

Phytoremediation is slower than traditional methods of removing heavy metals from soil but much less costly. Prevention of soil contamination is far less expensive than any kind of remediation and much better for the environment.

APPENDIX C – METHODS FOR ESTIMATING RECEIVING WATER QUALITY IMPACTS OF URBAN AND SUBURBAN DEVELOPMENT

This summary was developed by USEPA Region 5 - Chicago.

I. INTRODUCTION

This chapter provides an overview of practical methods for estimating short-term and long-term surface water quality impacts related to urban and suburban development sites. These methods may be used by the urban planner or developer to estimate the impacts on receiving waters from development which may result based on various planning conditions and assumptions. Using the approaches presented here, mitigation of water quality impacts may be tested based upon incorporation of various types of management practices.

II. IMPACTS OF URBAN AND SUBURBAN DEVELOPMENT

There are two principal types of water quality impacts typically associated with urban and suburban development. The first includes the impacts related to the construction phase of development as soils which are destabilized due to clearing grading and excavation are subject to increased erosion by wind and water. Eroded soils associated with construction activity can be carried offsite and deposited in receiving waters such as lakes, rivers and wetlands. Adverse impacts related to these sediments include increased turbidity and habitat modification, including smothering of spawning beds. While the construction phase itself may be relatively short-lived, the impacts to receiving waters from poorly managed construction activities may be extremely severe and long-lasting, particularly to sensitive areas such as wetlands and inland lakes.

Once the construction phase is over, other receiving water quality impacts may become more pronounced due to potentially dramatic changes to the area's hydrology (reduced baseflow and exaggerated peak flow volumes), and the change in land use compared to predevelopment conditions. The increase in impervious areas causes a resultant increase in runoff rates and volumes. This can result in increased streambank erosion and associated water quality problems.

The increased runoff also accelerates the transport of land-borne pollutants into receiving waters. Typical pollutants which may be found in urban storm water at significant levels include heavy metals, oil and grease, pesticides, fertilizers and other nutrients, and toxic organic contaminants. Runoff from roadways and parking lots may cause significant elevations in receiving water temperatures during summer months. Winter road deicing activities can contribute high levels of chlorides or sediment.

In order to properly manage and maintain urban water resources, the impacts associated with new development must be carefully evaluated. Post-development impacts may be evaluated in terms of short-term (acute) impacts, and long-term (chronic) impacts. Short term impacts include the changes to a receiving water's

chemistry, hydrology, temperature, etc, caused by individual runoff events, and are typically on a timescale of hours to days. Long-term impacts are those which are manifested in the weeks-to-years timescale, and include changes to the dry and wet weather hydrology, streambank morphology, and water chemistry of the receiving water. Long-term chemical impacts are most critical for receiving waters with longer residence times such as lakes and wetlands, and for slower moving stream segments.

In terms of the changes to a receiving water's chemistry due to urban runoff, pollutant concentrations are best used to evaluate short-term effects, while pollutant loadings are appropriate for assessing long-term impacts. Land use planners and developers need to understand these impacts and carefully plan in order to mitigate the negative water quality impacts of development. Part of the analysis should be to evaluate changes in both the annual mass of pollutants exported from a developing area (pollutant loading), and instream pollutant concentration related to runoff from new development or redevelopment.

Loading estimates may focus on nutrients such as phosphorus and nitrogen which contribute to algal blooms in lakes and ponds when the assimilative capacity is exceeded. Estimated loadings can be compared with any existing load allocation limitations for a given receiving water. Even when load allocations do not currently exist, loading estimates are very useful for predicting gross changes in the export of various parameters (sediment, oxygen demanding substances, toxic metals and organics, nutrients), and allow for the analysis of various best management practice (BMP) alternatives to modulate any increased loading of pollutants.

Concentration estimates can be compared with applicable State water quality standards to provide an indication of the likelihood that those standards will be exceeded as a result of storm water discharges. This analysis will help in the planning of BMPs to reduce short term impacts such as acute aquatic toxicity, biochemical oxygen demand and bacteria.

III. METHODS

The following is a summary of three methods which may be used to estimate water quality impacts of new development with respect to increased pollutant loading and pollutant concentration.

1. SIMPLE METHOD AND LOADING FUNCTIONS

Pollutant export estimates for a wide variety of pollutants under various planning assumptions can be estimated using the Simple Method (Schueler, 1987). The method is very easy to use as it requires only information which is readily available and does not involve the use of computer models to calculate load estimates. It is recommended that the method be limited in application to sites less than 1 square mile in area.

The annual mass export of a given pollutant in urban runoff may be estimated by the following basic form of the Simple Method:

(EQ 1) $L = (P)(P_j)(R_v)(C)(A)(0.227)$ - (where concentration is in mg/l), or

(EQ 1a) $L = (P)(P_j)(R_v)(C)(A)(0.000227)$ - (where concentration is in ug/l)

where:

- L = annual mass of pollutant export (lbs/yr)
- P = annual precipitation (inches)
- P_j = correction factor for smaller storms which do not produce runoff (dimensionless)
- R_v = runoff coefficient (dimensionless)
- C = average concentration of pollutant
- A = site area (acres)

Annual precipitation Where site specific values for **P** are not available these can be estimated from Figure 1 and Table 1. In Illinois, reasonable estimates fall between 30 inches per year in the northern and central parts of the State to 42 inches per year in the extreme southern section.

FIGURE 1 Rain Zones for the United States (EPA, 1989)

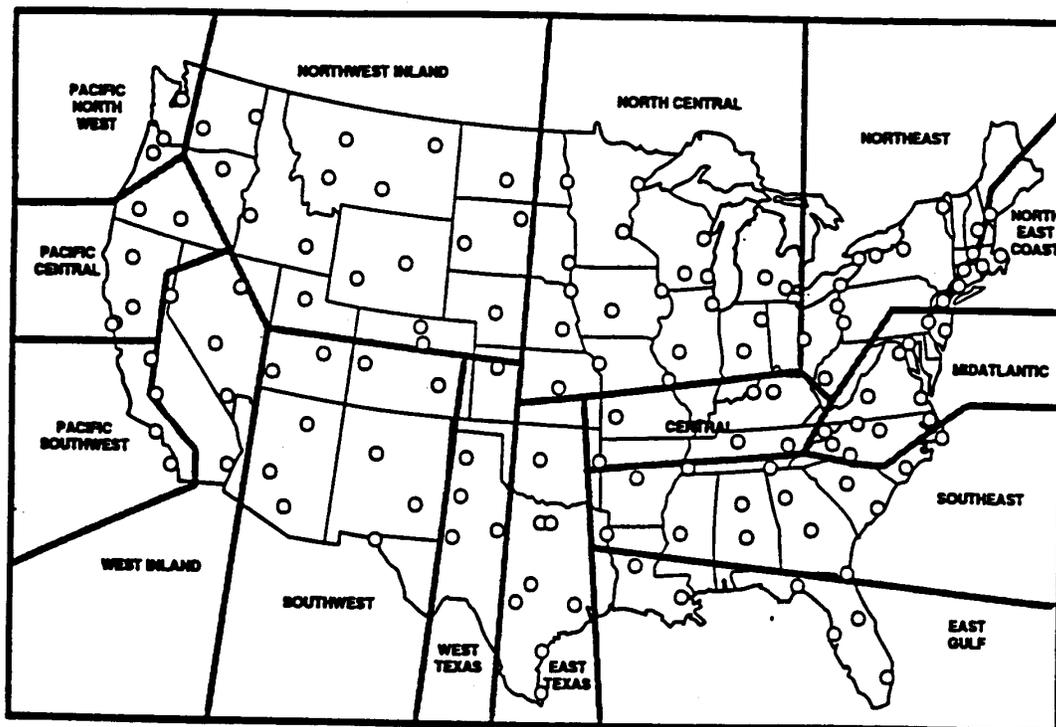

TABLE 1 *Typical Values for Annual Precipitation
in Rain Zones of the United States (EPA, 1989)*

<i>RAIN ZONE</i>	<i>NUMBER OF STORMS</i>	<i>COV</i>	<i>PRECIP (IN)</i>	<i>COV</i>
<i>Northeast</i>	<i>70</i>	<i>0.13</i>	<i>34.6</i>	<i>0.18</i>
<i>Northeast-Coastal</i>	<i>62</i>	<i>0.12</i>	<i>41.4</i>	<i>0.21</i>
<i>Mid-Atlantic</i>	<i>62</i>	<i>0.13</i>	<i>39.5</i>	<i>0.18</i>
<i>Central</i>	<i>68</i>	<i>0.14</i>	<i>41.9</i>	<i>0.19</i>
<i>North Central</i>	<i>55</i>	<i>0.16</i>	<i>29.8</i>	<i>0.22</i>
<i>Southeast</i>	<i>65</i>	<i>0.15</i>	<i>49.0</i>	<i>0.20</i>
<i>East Gulf</i>	<i>68</i>	<i>0.17</i>	<i>53.7</i>	<i>0.23</i>
<i>East Texas</i>	<i>41</i>	<i>0.22</i>	<i>31.2</i>	<i>0.29</i>
<i>West Texas</i>	<i>30</i>	<i>0.27</i>	<i>17.3</i>	<i>0.33</i>
<i>Southwest</i>	<i>20</i>	<i>0.30</i>	<i>7.4</i>	<i>0.37</i>
<i>West Inland</i>	<i>14</i>	<i>0.38</i>	<i>4.9</i>	<i>0.43</i>
<i>Pacific South</i>	<i>19</i>	<i>0.36</i>	<i>10.2</i>	<i>0.42</i>
<i>Northwest Inland</i>	<i>31</i>	<i>0.23</i>	<i>11.5</i>	<i>0.29</i>
<i>Pacific Central</i>	<i>32</i>	<i>0.26</i>	<i>18.4</i>	<i>0.33</i>
<i>Pacific Northwest</i>	<i>71</i>	<i>0.15</i>	<i>35.7</i>	<i>0.19</i>

COV = Coefficient of Variation = Standard Deviation/Mean

Correction Factor This factor is used to account for smaller storms which produce no runoff. The value of P_j may be estimated to be 0.9 where more precise data are unavailable.

Runoff Coefficient R_v represents that fraction of precipitation which appears as runoff. This may be estimated from the following:

$$(EQ 2) \quad R_v = 0.05 + 0.009(I) \quad (\text{Schueler, 1987})$$

where I is the impervious area for the site expressed as percent. I may be estimated by summing the area of impervious surfaces dividing by the total area.

Alternatively, I may be estimated for residential areas by:

$$(EQ 3) \quad I = 9(PD)^{1/2} \quad (\text{Shelly, 1988})$$

where PD is the population density in persons/acre.

Pollutant Concentration The concentration of pollutant C , may be determined from flow-weighted composite samples representative of annual average values in urban runoff from a given area. Where such data are not available, estimates may be based on data from the NURP database or other reliable sources. A table of C values compiled from NURP data is provided in Table 2. Other data on pollutant concentrations (Schueler, 1987), are presented in Tables 3 and 4.

TABLE 2 **Water Quality Characteristics of
Urban Runoff from NURP (U.S. EPA, 1983)**

<i>Pollutant</i>	<i>For Media Urban Site</i>	<i>For 90th Percentile Urban Site</i>	<i>Coefficient of Variation</i>
<i>TSS (mg/l)</i>	100	300	1-2
<i>BOD (mg/l)</i>	9	15	0.5-1.0
<i>COD (mg/l)</i>	65	140	0.5-1.0
<i>Tot. P (mg/l)</i>	0.33	0.70	0.5-1.0
<i>Sol. P (mg/l)</i>	0.12	0.21	0.5-1.0

Lead ug/l	33	0.99	27	1.32	29	0.81	--	--
Zinc ug/l	135	0.84	154	0.78	226	1.07	195	0.66

Source: NURP (EPA 1983)

TABLE 4 Concentration Values for Hardwood Forest (OWML, 1983)

Pollutant	Concentration
COD (mg/l)	>40
Tot. P (mg/l)	0.15
Sol. P (mg/l)	0.04
TKN (mg/l)	0.61
NO ₂ -N (mg/l)	0.17

EXAMPLE 1

A proposed 25 acre development in Northeastern Illinois would convert a woodland area ($I = 2\%$) to single family homes and townhouses. The total imperviousness would be 40%. Estimate the post-development increases in phosphorus and total Kjeldahl nitrogen (TKN) loadings.

Discussion

The annual precipitation is assumed to be 30 inches/year (Table 1). The runoff coefficient is calculated from EQ 2.

Prior to development, $I = 2\%$:

$$R_v = 0.05 + 0.009(2) = 0.068$$

After development:

$$R_v = 0.05 + 0.009(40) = 0.41$$

The concentration values C , are taken from Tables 3 and 4. (Mean NURP concentration values are assumed)

<u>Parameter</u>	<u>Pre-development</u>	<u>Post-development</u>
P	30 inches/year	30 inches/year
P_j	0.9	0.9
R_v	0.068	0.41
C (TKN)	0.61 mg/l	1.5 mg/l
C (total P)	0.15 mg/l	0.33 mg/l
A	25 acres	25 acres

Annual loadings are computed from EQ. 1:

Pre-development:

$$TKN = [(30 \text{ in/yr})(0.9)(0.068)(0.61 \text{ mg/l})(25 \text{ acres})(0.227)] = \underline{6.4 \text{ lbs/yr}}$$

$$P\text{-total} = [(30 \text{ in/yr})(0.9)(0.068)(0.15 \text{ mg/l})(25 \text{ acres})(0.227)] = \underline{1.6 \text{ lbs/yr}}$$

Post-development:

$$TKN = [(30 \text{ in/yr})(0.9)(0.41)(1.5 \text{ mg/l})(25 \text{ acres})(0.227)] = \underline{94.2 \text{ lbs/yr}}$$

$$P\text{-total} = [(30 \text{ in/yr})(0.9)(0.41)(0.33 \text{ mg/l})(25 \text{ acres})(0.227)] = \underline{20.7 \text{ lbs/yr}}$$

Results:

<u>Parameter</u>	<u>Pre-devel.</u>	<u>Post-devel.</u>	<u>Increase</u>
TKN	6.4 lbs/yr	94.2 lbs/yr	1472%
P-total	1.6 lbs/yr	20.7 lbs/yr	1294%

EXAMPLE 2

For the above example, what would be the post development nutrient increase if the total imperviousness were limited to 25%?

Discussion

From Equation 2, $R_v = 0.28$. From Equation 1, the post development increase would be:

<u>Parameter</u>	<u>Pre-devel.</u>	<u>Post-devel.</u>	<u>% Increase</u>
TKN	6.4 lbs/yr	64.3 lbs/yr	1000
P-total	1.6 lbs/yr	14.1 lbs/yr	884

EXAMPLE 3

Suggest a BMP or group of BMPs which could potentially limit the export of total phosphorus to within 50 % of pre-development levels.

Discussion

Table 15 provides a summary of pollutant removal efficiencies for various storm water runoff control practices. Wet ponds or multiple pond systems are the most reliable practices for controlling nutrients in runoff, and are also generally effective in removing other pollutants of concern.

Loading Functions The simple method may be used to convert typical concentration values to estimates of annual mass loadings. Also known as loading functions, these estimates can be based upon unit area for various land use types and per cent site imperviousness, or other similar constants. Loading functions allow for a direct estimation of pollutant loading for various land use types. Table 4 presents calculated loading functions from various land use types.

TABLE 4 Calculated Pollutant Mass Loadings for Various Land Uses

(Pounds/Acre/Year)

Land Use	I	Total Phos.	TKN	BOD 5-day	Zinc	Lead
Rural Residential	0	0.10	0.45	2.70	0.05	0.04
	5	0.19	0.86	5.16	0.09	0.08
	10	0.28	1.27	7.62	0.14	0.12
Large Lot Single Family	10	0.28	1.27	7.62	0.04	0.12
	15	0.38	1.73	10.4	0.18	0.17
	20	0.46	2.09	12.5	0.22	0.20
Medium Density Single Family	20	0.46	2.09	12.5	0.22	0.20
	25	0.55	2.50	15.0	0.27	0.24

¹ $P=30$ inches, $P_f=0.9$, $R_v=0.05+0.009(I)$, $A= 1$ acre,

$C=$ mean NURP values from Table 2

Similar loading functions can be made using the data in Table 3 or other appropriate data.

Total annual loads are estimated by multiplying the area associated with each given land use type by the loading function for that land use:

$$(EQ. 4) \quad L = \text{SUM}(L_x)(A_x)$$

where:

- L = total loading (lbs/yr)
- L_x = loading function for land use x (lbs/acre/yr)
- A_x = area of land use x (acre)

In another variation of the Simple Method, Heaney (Mills et al, 1985) has developed a loading function based on population density and street cleaning frequency:

$$(EQ.5) \quad L_x = (a_x)(F_x)(Y_x)(P)$$

where:

- L_x = loading function for land use x (lbs/acre)
- a_x = pollutant concentration factor (lbs/acre/in)
- F_x = population density function
- Y_x = street cleaning factor
- P = annual precipitation (inches)

Total loading is calculated using EQ. 5. Typical a_x values are given in Table 5.

**TABLE 5 Pollutant Concentration Factors (a_x)
For use in EQ 5**

Land Use	BOD	TSS	PO ₄	Nit.
Residential	0.78	16	0.033	0.13
Commercial	3.13	22	0.073	0.29
Industrial	1.18	29	0.069	0.27
Other Developed	0.11	2.7	0.009	0.06

The population density function, F_x is a dimensionless parameter. Typical empirical values for F_x adapted from Heaney et al. are:

1.0 for commercial and industrial development, and

$$(EQ. 6) \quad 0.142 + 0.134 [0.405(PD)]^{0.54} \text{ for residential}$$

where:

PD = population density (persons/acre)

The street cleaning factor is based upon the street sweeping interval in days (**N_s**):

Y_x = **N_s/20** for **N_s < 20** days

Y_x = **1.0** for **N_s > 20** days

EXAMPLE 4

Referring to Example 1, assume that the population density is 25 persons/acre and that street sweeping is performed 1/month, what is the annual nitrogen and phosphorus loading from the development as predicted from EQ. 4 ? How does this compare with the prediction from Example 1 ?

ANSWER

From TABLE 4, **a_x** is 0.033 (lbs/acre/in).

From EQ. 6, the population density function, **F_x** = 0.87

Y_x is set to 1.0, since street sweeping frequency is less than 1/20 days.

P = 30 in/yr.

From EQ 5, the phosphorus loading function is:

L_x = (0.033 lbs/acre-inch)(0.87)(1.0)(30 in/yr) = 0.86 lbs/acre-yr

The total annual load from EQ 3 is:

L = (25 acres)(0.86 lbs/acre-yr) = 22 lbs/yr (Using the simple method in Example 1 predicted 20.7 lbs/yr)

2. PHOSPHORUS LOAD ALLOCATIONS - THE MAINE DEP METHOD

The Maine Department of Environmental Protection has developed a detailed application of the loading functions method for determining changes in phosphorus loadings which may be expected as a result of different urban and suburban development scenarios (Dennis et al. 1989). Estimated phosphorus loadings can be compared with specified phosphorus loading allocations for Maine lakes. In addition, the procedure allows for the estimation of phosphorus loading mitigation, based on the use of various combinations of BMPS. By use of simple desk-top calculations, planners

and developers are able to estimate in advance whether proposed development areas will comply with the State's phosphorus loading allocations.

The acceptable increase in phosphorus export is determined by:

$$(EQ. 7) \quad L_p = (FC)/D$$

where:

L_p = acceptable increase in the phosphorus loading function (lbs/acre/yr)

1F = phosphorus coefficient for the lake watershed (lbs/ppb/yr)

C = acceptable increase in lake phosphorus concentration (ppb)

D = future area to be developed over next 50 years in the watershed (acres)

¹ ***F factors have been determined for specific lakes in Maine. Similar targets may be established for waterbodies in other areas. In the absence of specific loading limitations, the process may be used to estimate the increase in phosphorus loading resulting from a proposed development.***

C , the acceptable increase in phosphorus concentration, is a function of existing water quality and the level of desired protection. C values are given in Table 6.

TABLE 6 C Values - Acceptable Increase in Lake Phosphorus Concentration (Maine DEP, 1989)

Water Quality Category	Lake Protection Level		
	High	Medium	Low
Outstanding	0.5	1.0	1.0
Good	1.0	1.5	2.0
Moderate/Stable	1.0	1.25	1.5
Moderate/Sensitive	0.75	1.0	1.25
Poor/Restorable	0.1	0.5	NA
Poor/Low Priority	2.0	4.0	6.0

D is determined as the total area minus already developed and undevelopable land (steep slopes, wetlands, parks, etc.) and multiplying by a development factor which

estimates the portion of undeveloped land which is likely to be developed. In Maine these development factors are:

0.20 - 0.35 for lake areas near growth centers

0.15 - 0.25 for lake areas subject to seasonal development

0.10 - 0.20 for lakes for which development is shoreline dependent

0.10 - 0.15 for lake areas not subject to development pressure

It is recommended that conservative upper estimates be used for development factors.

The permitted phosphorus export (PPE) for a site is simply:

$$(EQ. 8) \quad PPE = (L_p)(A)$$

where:

PPE = permitted phosphorus export for proposed development (lbs/acre)

A = the proposed area of the site (acres)

The proposed area of the development (A) should include all areas except those which are undevelopable such as wetlands > 1 acre, and steep slopes.

The total predicted phosphorus export (TE) for a development site is the summation of export values from roadways, individual houselots, multi-unit housing, commercial and industrial development. Credit is given for phosphorus control measures which are employed. The general equation for Phosphorus export is:

$$(EQ. 9) \quad (TE) = \text{summation } (RE) + (HE) + (CE)$$

where:

(TE) = total predicted phosphorus export

(RE) = phosphorus export from roadways

(HE) = phosphorus export from individual house lots

(CE) = phosphorus export from multi-unit housing, commercial, and industrial development,

Phosphorus Export from Residential Area Roadways (RE)

Road surface phosphorus export is determined as follows:

$$(EQ. 9) \quad (RE) = [(FT)(LBS)(TF_b)(TF_{wp})(TF_i)(TF_o)]/100$$

where:

(FT) = length of roadway being evaluated (feet)

(LBS) = annual export of phosphorus from 100 feet of roadway, before treatment

(TF_b) = treatment factor for buffer strips

(TF_{wp}) = treatment factor for wet ponds

(TF_i) = treatment factor for infiltration practice

(TF_o) = treatment factor for other treatment factor

The annual export per 100 feet of roadway is calculated as:

$$(EQ. 10) \quad (LBS) = (\text{road surface width})(0.012) + (\text{road ditch width})(0.004)$$

Treatment factors (TF) for all the above calculations and those that follow must be numbers between 0 and 1.0 which reflect the long term phosphorus removal efficiency of the treatment practice or practices employed. Tables in Appendix C-1 present some recommended values. Note that lower numbers reflect higher removal efficiencies. It is also evident that the calculation gives greater credit where redundant treatment practices are employed.

Phosphorus export from individual house lots (HE)

The annual phosphorus export from an individual houselot is calculated as:

$$(EQ. 11) \quad (HE) = (BP)(TF_b)(TF_{wp})(TF_i)(TF_o)$$

where:

(BP) = phosphorus export before treatment

(TF_b) = treatment factor for buffer strips

(TF_{wp}) = treatment factor for wet ponds

(TF_i) = treatment factor for infiltration practice

(TF_o) = treatment factor for other treatment factor

Table 11 presents (BP) values for different hydrologic groups

TABLE 11 Phosphorus Export (BP Values) From Lots Before Treatment - Residential

Hydrologic Group	Area Cleared per Lot		
	<10,000 ft	>10,000 ft	>15,000 ft
A	.27 (.2)	.30 (.30)	.35 (.35)
B	.32 (.40)	.39 (.46)	.49 (.54)
C	.34 (.48)	.44 (.56)	.58 (.67)
D	.36 (.62)	.47 (.62)	.62 (.74)

Note: Values in parentheses are appropriate for sites where more than 40% of timber volume has been harvested within the last 5 years.

Phosphorus Export from Multi-unit Housing, Commercial, and Industrial Development (CE)

Phosphorus Export from multi-unit housing, commercial, and industrial development is calculated as:

$$(EQ. 12) \quad (CE_x) = (L_x)((BL_x)(TF_b)(TF_{wp})(TF_i)(TF_o))$$

where:

(L_x) = altered land surface area (acres)

(BL_x) = additional phosphorus export per acre of altered land surface (lbs/acre)

(TF_b) = treatment factor for buffer strips

(TF_{wp}) = treatment factor for wet ponds

(TF_i) = treatment factor for infiltration practice

(TF_o) = treatment factor for other treatment factor

Values for additional phosphorus export associated with altered land uses are found in Table 12.

TABLE 12 Phosphorus Export from Altered Land Uses

<i>Land Use Category</i>	<i>Phosphorus Export Before Treatment</i>
<i>Lawn A</i>	<i>.30 lbs/acre</i>
<i>Lawn B</i>	<i>.65 lbs/acre</i>
<i>Lawn C</i>	<i>.97 lbs/acre</i>
<i>Lawn D</i>	<i>1.1 lbs/acre</i>
<i>Road Ditch</i>	<i>1.8 lbs/acre</i>
<i>Road Surface</i>	<i>5.3 lbs/acre</i>
<i>Impervious Surfaces</i>	<i>3.5 lbs/acre</i>

The total loading from multi-unit housing, commercial and industrial areas is the summation of all areas for various land use categories.

EXAMPLE 5

Referring to the proposed development in Example 1, consists of 40 single family units with an average lot size of 0.31 acres, and 29 townhouses with an average of 0.43 acres. The resident soil is Type C. All the runoff will be treated by a wet detention basin. Runoff from the townhouses and roads will also be treated by a 150 foot buffer strip with a slope of 12%. The wet detention basin will be designed with a length to width ratio of 3:1, and mean depth of 5 ft.

The total road length to be added as part of the subdivision is 1,100 feet. The road width is 38 feet with 4 foot shoulders. The main access road which is included in the total road length is 700 feet and has 5 foot ditches on each roadside.

Calculate the additional phosphorus export associated with the proposed development. Also calculate without treatment and compare with Examples 1 and 4.

Discussion

Referring to Appendix C-1, assume a treatment factor of 0.7 for buffer strips 0.5 for the wet detention pond. The analysis must consider the runoff from the houses and townhouses separately. Assuming that < 10,000 ft² cleared, phosphorus loading from the single-family dwellings is:

$$(HE) = (40 \text{ lots})(0.48\text{lbs/lot/yr})(0.5) = 9.6 \text{ lbs/yr}$$

From the townhouses:

$$(CE) = (29 \text{ lots})(0.43 \text{ acres/lot})(0.97 \text{ lbs/acre/yr})(0.5)(0.7) = 4.2 \text{ lbs/yr}$$

For the roadways, use EQ. 9:

$$(LBS) = [(38 + 4 + 4)(0.012)] + [(5 + 5)(0.004)] = 0.59 \text{ lbs/100 ft}$$

$$(RE) = (11)(0.59)(0.7)(0.5) = 2.3 \text{ lbs/yr}$$

The total additional phosphorus export is then:

$$HE + CE + RE = \underline{16.1 \text{ lbs/yr}}$$

Without treatment:

$$(HE) = (40 \text{ lots})(0.48 \text{ lbs/lot/yr}) = 19.2 \text{ lbs/yr}$$

From the townhouses:

$$(CE) = (29 \text{ lots})(0.43 \text{ acres/lot})(0.97 \text{ lbs/acre/yr}) = 12.1 \text{ lbs/yr}$$

For the roadways, use EQ. 9:

$$(LBS) = [(38 + 4 + 4)(0.012)] + [(5 + 5)(0.004)] = 0.59 \text{ lbs/100 ft}$$

$$(RE) = (11)(0.59) = 6.5 \text{ lbs/yr}$$

The total additional phosphorus export is then:

$$HE + CE + RE = \underline{37.8 \text{ lbs/yr}}$$

This is somewhat higher than the solutions to Examples 1 and 4 (20.7 lbs/year and 22 lbs/year, respectively).

EXAMPLE 6

A 7.4 acre office complex in an area with type B soils is proposed. The site includes 4.9 acres of lawn area. Rooftop accounts for 0.9 acres and 1.1 acre for parking, and 0.3 acres for road surface, and 0.2 acres for road ditch. Calculate the additional phosphorus export.

All flows are to be treated by a 100 ft buffer strip with 10% slope and a wet detention pond with a 4:1 length to width ratio and a mean depth of 4 feet.

Discussion

From Appendix C - 1, TABLES C - 1.1 and C - 1.2, the Treatment factors are 0.6 for the buffer strip and 0.48 for the wet pond. Phosphorus loadings from the various areas are from Table 12 and EQ 9. The total loading is:

$$(CE) = [(4.9)(0.65) + (0.9)(3.5) + (1.1)(3.5) + (0.3)(5.3) + (0.2)(3.5)] \times [(0.6)(0.48)] = \underline{2.77 \text{ lbs phosphorus/yr}}$$

Other pollutants

While the Maine procedure was conceived for use in loading estimates of a particular pollutant (phosphorus), and is specific to the State of Maine, the basic concept can be expanded for use with other pollutants of concern in any type of receiving water anywhere in the country. In order to adapt this procedure, the following types of information are necessary:

- Data on annual average loading per unit area for given types of land uses.
- Data on the treatment efficiency of various best management practices in reducing the loading of pollutants of concern.

Where available, these may be compared with target loading ceilings for pollutants of concern.

Table 13 summarizes data on concentrations of various pollutants in runoff from to urban catchments in Wisconsin (Bannerman et al, 1992). In Table 14 these are converted to annual pollutant load per acre, based on 30 inches of precipitation annually. These can be converted to lbs per square foot by dividing by 43,560.

EXAMPLE 7

Returning to Example 1 and Example 5. Assume that the single family units have roofs which are 2,400 square feet (0.055 acre), and the townhouse roofs are 3,000 square feet (0.069 acre). Residential driveways are assumed to average 610 square feet (0.014 acres). Parking for the townhouses consists of 11 lots at an average of 6,500 square feet (0.15 acres) each.

Calculate the zinc loading for the 25 acre single family/townhouse development, using the Tables 14 and 15, and alternatively, EQ 1, before treatment. How do the results compare?

Discussion

The total roof area is:

$$(40)(0.055) + (29)(0.069) = 4.2 \text{ acres rooftops}$$

Total driveway area is:

$$(40)(0.014 \text{ acres}) = 0.56 \text{ acres driveway}$$

Total parking lot area is:

$$(11)(0.15 \text{ acres}) = 1.65 \text{ acres parking lot.}$$

The area associated with the roadways (feeder street) is:

$$(38 + 4 + 4)(1,100) = 50,600 \text{ square feet or } 1.2 \text{ acres}$$

The remaining area is considered to be residential lawn:

$$25 - [4.2 + 0.56 + 1.65 + 1.2] = 17.4 \text{ acres residential lawn}$$

Loading estimates:

Referring to Table 14, the estimated loading rate from rooftops is assumed to be 1.04 lbs zinc/yr, and 0.68 lbs lead/yr. Total loading for the development is:

$$\text{Zinc} - (4.2 \text{ acres})(1.04 \text{ lbs/acre/yr}) = 4.24 \text{ lbs/yr}$$

$$\text{Lead} - (4.2 \text{ acres})(0.68 \text{ lbs/acre/yr}) = 2.86 \text{ lbs/yr}$$

The estimated loading rate from residential driveways is assumed to be 0.768 lbs zinc/acre/yr, and 0.136 lbs lead/acre/yr. Total loading from residential driveways is:

$$\text{Zinc} - (0.56 \text{ acres})(0.768 \text{ lbs/acre/yr}) = 0.43 \text{ lbs/yr}$$

$$\text{Lead} - (0.56 \text{ acres})(0.136 \text{ lbs/acre/yr}) = 0.076 \text{ lbs/yr}$$

The estimated loading rate from parking lots is 1.69 lbs zinc/acre/yr and 0.20 lbs lead/acre/yr (assume study area 2 - medium density residential). Total loading from parking lots is:

$$\text{Zinc} - (1.65 \text{ acres})(1.69 \text{ lbs/acre/yr}) = 2.60 \text{ lbs/yr}$$

$$\text{Lead} - (1.65 \text{ acres})(0.20 \text{ lbs/acre/yr}) = 0.33 \text{ lbs/yr}$$

The estimated loading rate from the feeder streets is 1.67 lbs zinc/acre/yr, and 0.26 lbs lead/acre/yr. Total loading is:

$$\text{Zinc} - (1.2 \text{ acres})(1.67 \text{ lbs/acre/yr}) = 2.00 \text{ lbs/yr}$$

$$\text{Lead} - (1.2 \text{ acres})(0.26 \text{ lbs/acre/yr}) = 0.31 \text{ lbs/yr}$$

The estimated loading rate from residential lawns is 0 for zinc and unknown for lead. Therefore, assume no significant increase in metals loading from these areas.

Summing the above the total loading from all areas is gives:

$$\underline{\text{Zinc}} - 4.24 + 0.43 + 2.60 + 2.00 = \underline{\mathbf{9.3 \text{ lbs/yr}}}$$

$$\underline{\text{Lead}} - 2.86 + 0.076 + 0.33 + 0.31 = \underline{\mathbf{3.6 \text{ lbs/yr}}}$$

Using EQ 1a, and referring back to Table 2 and Example 1:

$$\underline{\text{Zinc}} = (30 \text{ in/yr})(0.9)(0.068)(0.160 \text{ mg/l})(25 \text{ acres}) = \underline{\mathbf{7.3 \text{ lbs/yr}}}$$

$$\underline{\text{Lead}} = (30 \text{ in/yr})(0.9)(0.068)(0.144 \text{ mg/l})(25 \text{ acres}) = \underline{\mathbf{6.6 \text{ lbs/yr}}}$$

The methods provide reasonable agreement for the proposed development.

3. ESTIMATING ACUTE CONCENTRATIONS

The approaches outlined above offer tools for predicting changes in long-term loading rates of pollutants to surface waters as an aid to planning activities. These methods do not provide for estimating short term impacts of urban runoff. Such impacts are more properly viewed as the result of instream pollutant concentrations rather than average loading rates. Predicted instream concentrations can be compared with state water quality standards as a means of predicting water quality standards violations due to urban runoff.

Typically much more complex computer models are employed to predict short term wet weather impacts to receiving waters brought about by urbanization. These models integrate hydrological and instream chemical processes in order to estimate instream pollutant concentrations. Models such as STORM and SWMM require significant data input and site specific verification.

Analysis of data collected as part of the National Urban Runoff Program (NURP) indicates that event mean pollutant concentrations may adequately be specified as a lognormal distribution (EPA, 1986). Because of this, the expected concentration for a given probability for a given pollutant in urban runoff can be determined for a particular data set if the central tendency (median or mean value) and the variability (coefficient of variation or standard deviation) are known. This concentration can be compared to some reference concentration such as a water quality standard to indicate the likelihood that an acute water quality impact will occur in the receiving water. Alternatively, the probability that a given concentration level (such as a water quality standard) will be exceeded can be estimated.

The expected runoff concentration for pollutant x is:

$$(EQ. 13) \quad C_x = C_m (\exp [Z (\ln\{1+COV\})^2]^{1/2})$$

where:

* C_x = expected concentration of pollutant x

* Z = standard normal probability (for specified probability of occurrence)

* C_m = median pollutant concentration

* COV = coefficient of variation

* **For log-transformed data**

The probability that a specified concentration will be exceeded can be determined by substituting the concentration level of interest for C_x in EQ. 13, solving the equation for Z , and locating the associated probability for the calculated Z value:

(EQ. 14) $Z = (\ln[C_x/C_m]) / [(\ln(1+COV^2))^{1/2}]$

Z values for various probabilities of occurrence is presented in Table 16.

Median event mean concentrations and coefficients of variation for NURP data for all land use types are presented in Table 3. If sufficient local data are available these may also be used provided they are transformed into logrhythmic form. Illinois Water quality standards for various pollutants is presented in Table 17. For certain metals these are based on hardness.

TABLE 16 Z Values for Various Probabilities

Z Value	Probability of Exceedance
3.090	0.1%

TABLE 17 Illinois Water Quality Standards

Pollutant	Acute Standard	Chronic Standard
Arsenic (ug/l)	360	
Cadmium (ug/l)	$\exp[A + B \ln(H)]$ but not > 50ug/l A=-2.98, B=1.128	$\exp[A + B \ln(H)]$ A=-3.49, B=0.785
Hexavalent Chromium (ug/l)	16	11
Trivalent Chromium (ug/l)	$\exp[A + B \ln(H)]$ A=3.688, B=0.819	$\exp[A + B \ln(H)]$ A=1.561, B=0.819
Copper (ug/l)	$\exp[A + B \ln(H)]$ A=-1.46, B=0.942	$\exp[A + B \ln(H)]$ A=-1.47, B=0.855
Cyanide (ug/l)	22	5.2
Lead (ug/l)	$\exp[A + B \ln(H)]$ but not >100ug/l A=-1.46, B=1.273	NA
Mercury (ug/l)	0.5	NA
Barium (mg/l)	5.0	NA
Boron (mg/l)	1.0	NA
Chloride (mg/l)	500	NA
Fluoride (mg/l)	1.4	NA
Iron Mg/l)	1.0	NA
Manganese (mg/l)	1.0	NA
Nickel (mg/l)	1.0	NA
Phenols (mg/l)	0.1	NA
Selenium (mg/l)	1.0	NA
Silver (ug/l)	5.0	NA
Sulfate (mg/l)	500	NA
Total Dissolved Solids (mg/l)	1000	NA
Zinc (mg/l)	1.0	NA

H = Hardness

EXAMPLE 8

For the development described in Example 1, what is the probability that water quality standards will be violated for zinc and lead, assuming no treatment.

Answer

From Table 15, the acute water quality standard for lead is:

$$WQS_{acute} = \exp[-1.46 + 1.273(\ln(H))]$$

Assuming the Hardness = 100 mg/l, then:

$$WQS_{acute} = 82 \text{ ug/l lead}$$

From Table 15, the acute water quality standard for zinc is:

$$WQS_{acute} = 1.0 \text{ mg/l zinc}$$

From Table 3, the median concentrations and Coefficients of variation for lead and zinc are

$$\text{Lead: } C_m = 33 \text{ ug/l, } \text{COV} = 0.99$$

$$\text{Zinc: } C_m = 135 \text{ ug/l, } \text{COV} = 0.84$$

Applying EQ 14, the probability that lead and zinc water quality standards would be exceeded for any given storm (assuming no treatment or dilution) would be estimated to be:

$$\text{Lead: } Z = (\ln[82/33])/[(\ln(1+0.99)^2)]^{1/2}$$

$$Z = 0.77, \text{ which corresponds to an exceedance probability of 20 - 25\%}$$

$$\text{Zinc: } Z = (\ln[1000/135])/[(\ln(1+0.84)^2)]^{1/2}$$

$$Z = 1.81, \text{ which corresponds to an exceedance probability of less than 5\%}$$

APPENDIX D - NPDES PHASE II STORM WATER PERMIT PROGRAM FOR SMALL MUNICIPAL SEPARATE STORM SEWER SYSTEMS (MS4s)

INTRODUCTION

This appendix contains information on the National Pollutant Discharge Elimination System (NPDES) Phase II storm water permit program for small municipal separate storm sewer systems (MS4s). It contains the Storm Water Phase II Compliance Assistance Guide and a series of fact sheets developed by US Environmental Protection Agency (EPA) that give an overview of the Storm Water Phase II Final Rule and Small MS4 program and discuss the six required minimum control measures. Additional information from USEPA is available at www.epa.gov/npdes/stormwater. A copy of the Storm Water Phase II Final Rule (64 *FR* 68722) that appeared in the Federal Register is available at www.epa.gov/npdes/regulations/phase2.pdf.

This appendix also contains the General NPDES Permit No. ILR40 for Discharges from Small Municipal Separate Storm Sewer Systems and the Notice of Intent (NOI) for General Permit for Discharges from Small Municipal Separate Storm Sewer Systems. The ILR40 Permit and NOI have been provided by the Illinois Environmental Protection Agency (EPA) who is responsible for administering the program in Illinois. The NOI pdf file is in a read-only format, but a word fillable form is available on the CD in the IEPA Fillable Forms folder.

Questions about the program should be directed to the Illinois EPA-Division of Water Pollution Control - Permit Section #15, Bureau of Water, 1021 North Grand Avenue East, P.O. Box 19276, Springfield, IL 62794-9276, phone 217-782-0610, fax 217-782-9891.

The Permit Section website contains information on when a permit is needed, forms, and a list of contacts at Illinois EPA: www.epa.state.il.us/water/permits/waste-water/index.html

This section was updated in November 2002.

General NPDES Permit No. ILR40

Illinois Environmental Protection Agency
Division of Water Pollution Control
1021 North Grand East
P.O. Box 19276
Springfield, Illinois 62794-9276

NATIONAL POLLUTANT DISCHARGE ELIMINATION SYSTEM

General NPDES Permit For Discharges from Small Municipal Separate Storm Sewer Systems

Expiration Date:	February 29, 2008	Issue Date:	December 20, 2002
		Effective Date:	March 1, 2003

Discharges authorized by this General Permit: In compliance with the provisions of the Illinois Environmental Protection Act, the Illinois Pollution Control Board Rules and Regulations (35 Ill. Adm. Code, Subtitle C, Chapter 1) and the Clean Water Act, the following discharges may be authorized by this permit in accordance with the conditions herein:

Discharges of storm water from small municipal separate storm sewer systems, as defined and limited herein. Storm water means storm water runoff, snow melt runoff, and surface runoff and drainage.

This general permit regulates only storm water discharges. Other discharges such as process wastewater or cooling water shall be regulated by other NPDES permits.

Receiving waters: Discharges may be authorized to any surface water of the State.

To receive authorization to discharge under this general permit, a facility operator must submit an application as described in the permit conditions to the Illinois Environmental Protection Agency. Authorization, if granted, will be by letter and include a copy of this permit.

Thomas G. McSwiggin, P.E.
Manager, Permit Section
Division of Water Pollution Control

ATTACHMENT H. STANDARD CONDITIONS.....	Page 11

PART I. COVERAGE UNDER THIS PERMIT

A. Permit Area

This permit covers all areas of the State of Illinois.

B. Eligibility

1. This permit authorizes discharges of storm water from small municipal separate storm sewer systems (MS4s) as defined in 40 CFR 122.26(b)(16) as designated for permit authorization pursuant to 40 CFR 122.32.
2. This permit authorizes the following non-storm water discharges provided they have been determined not to be substantial contributors of pollutants to a particular small MS4 applying for coverage under this permit:
 - water line and fire hydrant flushing,
 - landscape irrigation water,
 - rising ground waters,
 - ground water infiltration,
 - pumped ground water,
 - discharges from potable water sources,
 - foundation drains,
 - air conditioning condensate,
 - irrigation water, (except for wastewater irrigation),
 - springs,
 - water from crawl space pumps,
 - footing drains,
 - storm sewer cleaning water,
 - water from individual residential car washing,
 - routine external building washdown which does not use detergents,
 - flows from riparian habitats and wetlands,
 - dechlorinated pH neutral swimming pool discharges,
 - residual street wash water,
 - discharges or flows from fire fighting activities
 - dechlorinated water reservoir discharges, and
 - pavement washwaters where spills or leaks of toxic or hazardous materials have not occurred (unless all spilled material has been removed).
3. Any municipality covered by this general permit is also granted automatic coverage under Permit No. ILR10 for the discharge of storm water associated with construction site activities for municipal construction projects disturbing one acre or more. The permittee shall comply with all the requirements of Permit ILR10 for all such construction projects.

C. Limitations on Coverage

The following discharges are not authorized by this permit:

1. Storm water discharges that are mixed with non-storm water or storm water associated with industrial activity unless such discharges are:
 - a. in compliance with a separate NPDES permit, or
 - b. identified by and in compliance with Part I.B.2 of this permit.

General NPDES Permit No. ILR40

2. Storm water discharges that the Agency determines are not appropriately covered by this general permit.

D. Obtaining Authorization

In order for storm water discharges from small municipal separate storm sewer systems to be authorized to discharge under this general permit, a discharger must:

1. Submit a Notice of Intent (NOI) in accordance with the requirements of Part II using an NOI form provided by the Agency (or a photocopy thereof) or the appropriate U.S. EPA NOI form.
2. Where the operator changes, or where a new operator is added after the submittal of an NOI under Part II, a new NOI must be submitted in accordance with Part II within 30 days of the change.
3. Unless notified by the Agency to the contrary, dischargers who submit an NOI in accordance with the requirements of this permit are authorized to discharge storm water from small municipal separate storm sewer systems under the terms and conditions of this permit 30 days after the date that the NOI is received. The Agency may deny coverage under this permit and require submittal of an application for an individual NPDES permit based on a review of the NOI or other information.

PART II. NOTICE OF INTENT REQUIREMENTS**A. Deadlines for Notification**

1. If you are an operator of a regulated small municipal separate storm sewer system designated under § 122.32(a)(1), you must apply for coverage under an NPDES permit, or apply for a modification of an existing NPDES permit by March 10, 2003.
2. If you are an operator of a regulated small municipal separate storm sewer system designated under § 122.32(a)(2), you must apply for coverage under an NPDES permit, or apply for a modification of an existing NPDES permit within 180 days of notice, from the Agency or by a later date as specified by the Agency.
3. Submitting a late NOI. You are not prohibited from submitting an NOI after the dates provided in Part II.A.1 and II.A.2. If a late NOI is submitted, your authorization is only for discharges that occur after permit coverage is granted. The Agency reserves the right to take appropriate enforcement actions for any unpermitted discharges.

B. Contents of Notice of Intent

Dischargers seeking coverage under this permit shall submit either the Illinois MS4 NOI form or the U.S. EPA MS4 NOI form. The Notice(s) of Intent shall be signed in accordance with Standard Condition 11 of this permit and shall include the following information:

1. The street address, county, and the latitude and longitude of the municipal office for which the notification is submitted;
2. The name, address, and telephone number of the operator(s) filing the NOI for permit coverage;
3. The name of the receiving water(s); and
4. The following shall be provided as an attachment to the NOI:
 - a. the best management practices (BMPs) to be implemented and the measurable goals for each of the storm water minimum control measures in paragraph IV. B. of this permit designed to reduce the discharge of pollutants to the maximum extent practicable;
 - b. the month and year in which you will start and fully implement each of the minimum control measures or indicate the frequency of the action;
 - c. the person or persons responsible for implementing or coordinating your storm water management program; and
 - d. identification of a local qualifying program if any.

C. The required information shall be submitted to the following address:

Illinois Environmental Protection Agency
Division of Water Pollution Control
Permit Section
Post Office Box 19276
Springfield, Illinois 62794-9276

D. Shared Responsibilities

You may partner with other MS4s to develop and implement your storm water management program. You may also jointly submit an NOI with one or more MS4s. Each MS4 must fill out the NOI form. The description of your storm water management program must clearly describe which permittees are responsible for implementing each of the control measures.

PART III. SPECIAL CONDITIONS

- A. Your discharges, alone or in combination with other sources, shall not cause or contribute to a violation of any applicable water quality standard outlined in 35 Ill. Adm. Code 302.
- B. If there is evidence indicating that the storm water discharges authorized by this permit cause, or have the reasonable potential to cause or contribute to a violation of water quality standard, you may be required to obtain an individual permit or an alternative general permit or the permit may be modified to include different limitations and/or requirements.
- C. If a total maximum daily load (TMDL) allocation or watershed management plan is approved for any waterbody into which you discharge, you must review your storm water management program to determine whether the TMDL or watershed management plan includes requirements for control of storm water discharges. If you are not meeting the TMDL allocations, you must modify your storm water management program to implement the TMDL or watershed management plan within eighteen months of notification by the Agency of the TMDL's approval. Where a TMDL or watershed management plan is approved, you must:
1. Determine whether the approved TMDL is for a pollutant likely to be found in storm water discharges from your MS4.
 2. Determine whether the TMDL includes a pollutant wasteload allocation (WLA) or other performance requirements specifically for storm water discharge from your MS4.
 3. Determine whether the TMDL addresses a flow regime likely to occur during periods of storm water discharge.
 4. After the determinations above have been made and if it is found that your MS4 must implement specific WLA provisions of the TMDL, assess whether the WLAs are being met through implementation of existing storm water control measures or if additional control measures are necessary.
 5. Document all control measures currently being implemented or planned to be implemented. Also include a schedule of implementation for all planned controls. Document the calculations or other evidence that shows that the WLA will be met.
 6. Describe and implement a monitoring program to determine whether the storm water controls are adequate to meet the WLA.
 7. If the evaluation shows that additional or modified controls are necessary, describe the type and schedule for the control additions/revisions. Continue Paragraphs 4 above through 7 until two continuous monitoring cycles show that the WLAs are being met or that WQ standards are being met.
- D. If this permit is not reissued or replaced prior to the expiration date, it will be administratively continued in accordance with the Administrative Procedures Act and remain in force and effect. Any permittee who was granted permit coverage prior to the expiration date will automatically remain covered by the continued permit until the earlier of:
1. Reissuance or replacement of this permit, at which time you must comply with the Notice of Intent conditions of the new permit to maintain authorization to discharge; or
 2. Your submittal of a Notice of Termination; or
 3. Issuance of an individual permit for your discharges; or
 4. A formal permit decision by the Agency not to reissue this general permit at which time you must seek coverage under an alternative general permit or an individual permit.
- E. The Agency may require any person authorized to discharge by this permit to apply for and obtain either an individual NPDES permit or an alternative NPDES general permit. Any interested person may petition the Agency to take action under this paragraph. The Agency may require any owner or operator authorized to discharge under this permit to apply for an individual NPDES permit only if the owner or operator has been notified in writing that a permit application is required. This notice shall include a brief statement of the reasons for this decision, an application form, a statement setting a deadline for the owner or operator to file the application, and a statement that on the effective date of the individual NPDES permit or the alternative general permit as it applies to the individual permittee, coverage under this general permit shall automatically terminate. The Agency may grant additional time to submit the application upon request of the applicant. If an owner or operator fails to submit in a timely manner an individual NPDES permit application required by the Agency under this paragraph, then the applicability of this permit to the individual NPDES permittee is automatically terminated at the end of the day specified for application submittal.

- F. Any owner or operator authorized by this permit may request to be excluded from the coverage of this permit by applying for an individual permit. The owner or operator shall submit an individual application with reasons supporting the request, in accordance with the requirements of 40 CFR 122.28, to the Agency. The request will be granted by issuing an individual permit or an alternative general permit if the reasons cited by the owner or operator are adequate to support the request.
- G. When an individual NPDES permit is issued to an owner or operator otherwise subject to this permit, or the owner or operator is approved for coverage under an alternative NPDES general permit, the applicability of this permit to the individual NPDES permittee is automatically terminated on the issue date of the individual permit or the date of approval for coverage under the alternative general permit, whichever the case may be.
- H. When an individual NPDES permit is denied to an owner or operator otherwise subject to this permit, or the owner or operator is denied coverage under an alternative NPDES general permit the applicability of this permit to the individual NPDES permitted is automatically terminated on the date of such denial, unless otherwise specified by the Agency.

PART IV. STORM WATER MANAGEMENT PROGRAMS

A. Requirements

You must develop, implement, and enforce a storm water management program designed to reduce the discharge of pollutants from your small municipal separate storm sewer system to the maximum extent practicable (MEP), to protect water quality, and to satisfy the appropriate water quality requirements of the Illinois Pollution Control Board Rules and Regulations (35 Ill. Adm. Code, Subtitle C, Chapter 1) and the Clean Water Act. Your storm water management program must include the minimum control measures described in section B of this Part. You must develop and implement your program by five years from your coverage date under this permit.

B. Minimum Control Measures

The 6 minimum control measures to be included in your storm water management program are:

1. Public education and outreach on storm water impacts

You must:

- a. implement a public education program to distribute educational materials to the community or conduct equivalent outreach activities about the impacts of storm water discharges on water bodies and the steps that the public can take to reduce pollutants in storm water runoff; and
- b. define appropriate BMPs for this minimum control measure and measurable goals for each BMP. These measurable goals must ensure the reduction of all of the pollutants of concern in your storm water discharges to the maximum extent practicable.

2. Public Involvement/Participation

You must:

- a. at a minimum, comply with State and local public notice requirements when implementing a public involvement/participation program; and
- b. define appropriate BMPs for this minimum control measure and measurable goals for each BMP, which must ensure the reduction of all of the pollutants of concern in your storm water discharges to the maximum extent practicable.

3. Illicit discharge detection and elimination

You must:

- a. develop, implement and enforce a program to detect and eliminate illicit discharges into your small MS4;
- b. develop, if not already completed, a storm sewer system map, showing the location of all outfalls and the names and location of all waters that receive discharges from those outfalls;
- c. to the extent allowable under state or local law, effectively prohibit, through ordinance, or other regulatory mechanism, non-storm water discharges into your storm sewer system and implement appropriate enforcement procedures and actions;
- d. develop, implement, and adequately fund a plan to detect and address non-storm water discharges, including illegal dumping, to your system;
- e. inform public employees, businesses, and the general public of hazards associated with illegal discharges and improper disposal of waste;

General NPDES Permit No. ILR40

- f. address the categories of non-storm water discharges listed in Section I.B.2 only if you identify them as significant contributor of pollutants to your small MS4 (discharges or flows from the fire fighting activities are excluded from the effective prohibition against non-storm water and need only be addressed where they are identified as significant sources of pollutants to waters of the United States); and
- g. define appropriate BMPs for this minimum control measure and measurable goals for each BMP. These measurable goals must ensure the reduction of all of the pollutants of concern in your storm water discharges to the maximum extent practicable.

4. Construction site storm water runoff control

You must:
