15. Supplementary Notes					
16. Abstract  In order to verify its mechanistic pavement design procedures and review and update the life-cycle cost models used in the pavement selection process, the Illinois Department of Transportation (IDOT) conducted pavement performance monitoring. IDOT's Bureau of Materials and Physical Research (BMPR) initially conducted performance monitoring on mechanistically-designed pavement contracts in the 1990s. In 2000, this effort was halted as BMPR experienced staffing shortages. BMPR resumed monitoring the performance of mechanistically-designed pavements in 2010. Pavement performance monitoring involves tracking distresses as they occur over time, and identifying the maintenance and rehabilitation activities that are performed on the contract.  A total of 105 contracts were monitored: 55 full-depth hot-mix asphalt (HMA) pavements, 24 jointed plain concrete pavements (JPCP), and 26 continuously reinforced concrete pavements (CRCP). Contracts were broken into sections depending on the number of lanes on the project and the number of different cross-sectional elements (i.e. thickness, joint spacing, etc.). Distress data, weighted average rut depth, weighted average ride quality, and weighted average traffic values are provided for each section. Historical patching quantities are also presented. Also, graphs of patching quantities and overlays are presented as a function of age for full-depth HMA pavements, JPCP, and CRCP.					
17. Key Words  mechanistic design, hot-mix asphalt, portland cement concrete, full-depth HMA pavements, jointed plain concrete pavements, continuously reinforced concrete pavements, pavement performance			18. Distribution Statement  No restrictions. This document is available to the public through the National Technical Information Service, Springfield, Virginia 22161.

## PAVEMENT PERFORMANCE MONITORING DATA – 2010

The Illinois Department of Transportation (IDOT) is committed to verifying its mechanistic pavement design procedures and reviewing and updating the life-cycle cost models used in the pavement selection process. IDOT's Bureau of Materials and Physical Research (BMPR) initially conducted performance monitoring on mechanistically-designed pavement sections in the 1990s. In 2000, this effort was halted as BMPR experienced staffing shortages. In 2010, BMPR resumed monitoring the performance of mechanistically-designed pavements. Performance monitoring involves tracking distresses as they occur over time, and identifying the maintenance and rehabilitation activities that are performed on the section.

Contracts were selected from previously monitored pavements, and filtered to reduce redundancies and span a wide range of pavement thicknesses with a good spread of locations throughout the state. In order to track pavement performance over the widest range of design variables, matrices were developed for each pavement type: full-depth HMA, JPCP, and CRCP. Within each pavement type, contracts were selected for inclusion in the matrix based on location in the state and pavement thickness. Districts 1 and 2 were considered northern districts; Districts 3 – 7 were considered central districts, and Districts 8 and 9 were considered southern districts. These groupings correspond to the pavement temperatures found on the HMA Mixture Temperature map in the full-depth HMA design procedure (1). The central districts were further broken down into central-north (Districts 3 - 4) and central-south (Districts 5 - 7). Mechanistically-designed pavements constructed between 1986 and 2005 were reviewed. Priority placement in the matrix was given to pavement sections that had been previously monitored by BMPR. The matrix for full-depth HMA pavements is shown in Table 1, the JPCP matrix in Table 2, and the CRCP matrix in Table 3.

A total of 105 contracts are being monitored: 55 full-depth HMA, 24 JPCP, and 26 CRCP. The majority of these contracts (over 800 lane-miles of pavement) were surveyed in the field in 2010, while an additional 350 lane-miles of high-traffic volume roadways were reviewed on video to ensure the safety of IDOT personnel. All distresses were collected in the surveys. Appendix A, *Bureau of Materials and Physical Research Pavement Distress Manual*, documents the various distresses and the severity levels identified and summarized for each pavement type.

Field surveys were summarized upon survey completion. Distress summaries for completed sections are shown in Appendix B, *Performance Monitoring Section Summaries for Full-Depth HMA Pavements*; Appendix C, *Performance Monitoring Section Summaries for JPCP*; and Appendix D, *Performance Monitoring Section Summaries for CRCP*. Summaries are presented for each original construction contract on one or more sheets, depending upon the number of lanes in the project and the number of different cross-sectional elements (i.e., thickness, joint spacing, etc.) within a contract. The limits of the gross length of each section are noted on the summary sheet. Note that these are approximate limits based on key route mileposts from the Office of Planning and Programming's I-ROADS database. Actual survey quantities represent the net length of each section surveyed, which may vary from the gross length due to omissions for bridges, alternative pavement sections, etc. Each summary sheet is considered an individual section.

Once field surveys were completed, districts were contacted to verify maintenance and rehabilitation activities performed on the monitored sections. Dates and limits of overlays were confirmed and are reported on the individual distress summaries. When reviewing rehabilitation data, some projects received overlays that did not extend over the entire limits of the monitored section. Sections that received an overlay over less than 25 percent of the monitored section limits were considered to be bare (i.e., did not receive an overlay), while sections that received an overlay over more than 75 percent of the monitored section limits were considered to be overlaid in their entirety. Sections that received an overlay covering between 25 and 75 percent of the monitored section limits were further split into two sections and distresses summarized individually.

Distress summaries also include weighted average rut depth, weighted average ride quality, and weighted average traffic values for each section. Rut depth, ride quality, and traffic data were obtained from the Office of Planning and Programming, and represent the latest year data was available, generally 2009 or 2010, depending upon the data collection schedule.

An analysis was completed to review patching quantities as a function of age for each pavement type. Data was summarized by contract. Patching quantities from previous distress surveys are shown in Appendix E, *Patching Quantities from Full-Depth HMA Pavement Historical Distress Surveys*; Appendix F, *Patching Quantities from JPCP Historical Distress Surveys*; and Appendix G, *Patching Quantities from CRCP Historical Distress Surveys*. Using data from Appendix B and Appendix E, an analysis of patching quantities as a function of age on full-depth HMA pavements was made and is shown in Figures 1 and 4. Similarly, data from Appendix C and Appendix F was used to create an analysis of patching quantities as a function of age for JPCP in Figures 2 and 5, and data from Appendix D and Appendix G was used to create an analysis of patching quantities as a function of age for CRCP in Figures 3 and 6. Figures 1 – 3 are presented over the complete 45-year life-cycle analysis period; whereas Figures 4 – 6 are magnified versions for the first 25 years of the life-cycle analysis period, which corresponds to the maximum age of the sections surveyed. Note that each point shown in Figures 1 – 6 represents a distress survey; a contract may have more than one point depending on the amount of historical data available.

Analyses of overlays on the different pavement types were also completed. An analysis of overlays on HMA pavements as a function of age is shown in Figure 7, an analysis of overlays on JPCP as a function of age is shown in Figure 8, and an analysis of overlays on CRCP as a function of age is shown in Figure 9. Note that in Figures 7 – 9 each contract may be represented more than once, depending on the number of section distress summaries per contract.

# **Asphalt Concrete Surfaced Pavement**

# Bureau of Materials and Physical Research Pavement Distress Manual

## ALLIGATOR OR FATIGUE CRACKING

### Description:

Alligator or fatigue cracking is a series of interconnecting cracks forming many-sided, sharp-edged pieces. The cracks develop a pattern resembling chicken wire or the skin of an alligator. The longest side of the pieces is usually less than one-foot in length. Fatigue or alligator cracking is a load associated distress. Pattern-type cracking occurring over an area not subjected to traffic load is rated as "Block Cracking".

### Severity Levels:

- L - Longitudinal disconnected hairline cracks running parallel to each other. The cracks are not spalled. Initially there may only be a single crack in the wheel path. Defined as Class 1 cracking at AASHO Road Test.
- M - Further development of low severity fatigue cracking into a pattern of pieces formed by cracks that may be sealed. Defined as Class 2 cracking at AASHO Road Test.
- H - Medium fatigue cracking has progressed so that pieces are more severely spalled at the edges and loosened until the cells rock under traffic. Pumping may exist. Defined as Class 3 cracking at AASHO Road Test.

### How to Record:

Alligator and fatigue cracking is measured as the length of pavement (lane feet) where the distress occurs anywhere within the lane. The highest severity level present within the width of the pavement should be recorded.

Bureau of Materials and Physical Research  
Pavement Distress Manual

High Severity Alligator Cracking

# Bureau of Materials and Physical Research Pavement Distress Manual

## ASPHALT BLEEDING

### Description:

Asphalt bleeding is the presence of excess asphalt material on the pavement surface. It usually occurs in the wheelpaths. Asphalt material spilled onto the surface from sealing operations or moving vehicles should not be included.

### Severity Levels:

No degrees of severity are defined.

### How to Record:

Asphalt bleeding is recorded as the length of pavement (lane feet) where the distress occurs anywhere within the lane.

Asphalt Bleeding in Wheelpaths

# Bureau of Materials and Physical Research Pavement Distress Manual

## BELT-CRACKING

### Description:

Belt-cracking consists of two parallel cracks, two to eight inches apart. Usually one crack forms first and then with time and/or traffic, a second or parallel crack forms. The second crack may be the same length as the first crack, but usually occurs only along a portion of the first crack.

Belt-cracking usually is found in association with the following distresses: Transverse Joint Reflection Cracking, Transverse Cracking, Reflective Widening Cracking, and Reflected Patch Cracking.

### Severity Levels:

- L - One or both parallel cracks are very tight and barely visible to the eye, or one crack is definitely wider than the other.
- M - Both cracks have the same crack width. The area between the parallel cracks may be slightly depressed (less than or equal to .10"), but is in good overall condition.
- H - The following conditions may exist alone or in combination: (1) the area between the parallel cracks is depressed noticeably, (2) the area between cracks is severely distressed and material may be loose or missing, (3) maintenance has been performed.

### How to Record:

Belt-cracking is measured in the number of occurrences. A crack exhibiting various levels of severity is to be recorded as the highest level of severity present.

Bureau of Materials and Physical Research  
Pavement Distress Manual

Medium Severity Belt Cracking

High Severity Belt Cracking

# Bureau of Materials and Physical Research Pavement Distress Manual

## BLOCK CRACKING

### Description:

Block cracking, sometimes called area cracking, divides the asphalt surface into approximately rectangular pieces. These blocks range in size from approximately 1-ft<sup>2</sup> to 100 ft<sup>2</sup>. Cracking into larger blocks is generally rated as longitudinal and/or transverse cracking. Block cracking normally occurs over a large portion of the pavement area. The cracks usually extend only a short distance into the bituminous surface. Block cracking should not be mistaken for Fatigue Cracking or "Alligator Cracking", which forms smaller, many-sided pieces having sharp angles.

### Severity Levels:

- L - Cracks are tight (mean width less than or equal to 1/4") with minor or no spalling present.
- M - Crack width is between 1/4" and 1/2". Cracks may be moderately spalled. Low severity random parallel cracking may exist near the crack or at the intersection of cracks.
- H - One or more of the following conditions exist: (1) crack width is greater than 1/2", (2) crack is severely spalled, (3) medium or severe random parallel cracking exists near the crack or at the intersection of the cracks, (4) major sealing or other major maintenance activity has been performed.

### How to Record:

Block cracking is measured as the length of pavement (lane feet) where the distress occurs anywhere within the lane. If a length of pavement exhibits more than one severity level, it should be subdivided into lengths exhibiting one predominate severity level.

### Note:

Most sealed cracks are of high severity because of original crack width and/or severe spalling. In some cases, low and medium severity cracks have been sealed for preventive maintenance.

Bureau of Materials and Physical Research  
Pavement Distress Manual

Medium Severity Block Cracking

High Severity Block Cracking

Bureau of Materials and Physical Research  
Pavement Distress Manual

CENTER OF LANE CRACKING

Description:

Center of lane cracking is a longitudinal crack situated in the center of a lane. This crack is very straight in nature and does not wander or meander. All other longitudinal cracks should be identified as "Longitudinal Cracking".

Severity Levels:

- L - Cracks are tight (mean width less than or equal to 1/4") with minor or no spalling present.
- M - Crack width is between 1/4" and 1/2". Cracks may be moderately spalled. Low severity random parallel cracking may exist near the crack or at the intersection of cracks.
- H - One or more of the following conditions exist: (1) crack width is greater than 1/2", (2) crack is severely spalled, (3) medium or severe random parallel cracking exists near the crack or at the intersection of cracks, (4) major sealing or other major maintenance activity has been performed.

How to Record:

Center of lane cracking is measured in lineal feet. The length and severity level of each crack should be identified and recorded. If the crack does not have the same severity level along its entire length, each general portion should be recorded separately.

Note:

Most sealed cracks are of high severity because of original crack width and/or severe spalling. In some cases, low and medium severity cracks have been sealed for preventive maintenance.

# Bureau of Materials and Physical Research Pavement Distress Manual

## CENTERLINE CRACKING

### Description:

Centerline cracking is located along the centerline of two-lane pavements and between lanes of pavements with three or more lanes. The joint formed by the bituminous paving operation is included in this distress. The reflection crack caused by the centerline joint in the underlying Portland cement concrete (PCC) is also included.

### Severity Levels:

- L - Cracks are tight (mean width less than or equal to 1/4") with minor or no spalling present.
- M - Crack width is between 1/4" and 1/2". Cracks may be moderately spalled. Low severity random parallel cracking may exist near the crack or at the intersection of cracks.
- H - One or more of the following conditions exist: (1) crack width is greater than 1/2", (2) crack is severely spalled, (3) medium or severe random parallel cracking exists near the crack or at the intersection of cracks, (4) major sealing or other major maintenance activity has been performed.

### How to Record:

The total lengths, in feet, of each severity level existing in the sample unit are recorded.

### Note:

Most sealed cracks are of high severity because of original crack width and/or severe spalling. In some cases, low and medium severity cracks have been sealed for preventive maintenance.

Bureau of Materials and Physical Research  
Pavement Distress Manual

Low Severity Centerline Cracking

High Severity Centerline Cracking

Bureau of Materials and Physical Research  
Pavement Distress Manual

LONGITUDINAL CRACKING

Description:

Longitudinal cracks are parallel to the pavement's centerline. They can appear anywhere between the centerline and the outer edge of the outer wheelpath. This crack may be fairly straight or may meander within a lane width. Very straight cracks located in the exact center of the lane are not included as these are identified as "Center of Lane Cracking".

Severity Levels:

- L - Cracks are tight (mean width less than or equal to 1/4") with minor or no spalling present.
- M - Crack width is between 1/4" and 1/2". Cracks may be moderately spalled. Low severity random parallel cracking may exist near the crack or at the intersection of cracks.
- H - One or more of the following conditions exist: (1) crack width is greater than 1/2", (2) crack is severely spalled, (3) medium or severe random parallel cracking exists near the crack or at the intersection of cracks, (4) major sealing or other major maintenance activity has been performed.

How to Record:

Longitudinal cracking is measured in lineal feet. The length and severity level of each crack should be identified and recorded. If the crack does not have the same severity level along its entire length, each general portion should be recorded separately.

Note:

Most sealed cracks are of high severity because of original crack width and/or severe spalling. In some cases, low and medium severity cracks have been sealed for preventive maintenance.

Bureau of Materials and Physical Research  
Pavement Distress Manual

OVERLAID PATCH DETERIORATION

Description:

Overlaid patch deterioration occurs when a patch in the underlying pavement has reflected through the bituminous overlay. Only the area between the reflected cracks is to be evaluated.

Severity Levels:

- L - Cracks are tight and the bituminous overlay is in very good condition in the vicinity of the cracks.
- M - The bituminous overlay is somewhat deteriorated, having medium level of severity for any type of distress described in this manual.
- H - The bituminous overlay is badly deteriorated in the area of the patch and in need of maintenance.

How to Record:

Each reflected patch is measured in square feet of surface and is rated to the highest level of distress present. The reflected cracks are rated and recorded separately as "Reflected Patch Cracking". Only those patches whose edges have reflected through the overlay enough to determine the area should be rated. For jointed pavements, both cracks should extend at least halfway across a lane.

Bureau of Materials and Physical Research  
Pavement Distress Manual

Low Severity Overlaid Patch Deterioration

# Bureau of Materials and Physical Research Pavement Distress Manual

## PERMANENT PATCH DETERIORATION

### Description:

A permanent patch deterioration is an area where the pavement has been removed and replaced with either similar or different material.

### Severity Levels:

L - Patch is in very good condition and is performing satisfactorily.

M - Patch is somewhat deteriorated, having low to medium levels of any type of distress described in this manual.

H - Patch is badly deteriorated and soon needs replacement.

### How to Record:

Each patch is measured in square feet of surface and is rated to the highest level of distress present. Even if a patch is in excellent condition, it is still rated low severity.

Bureau of Materials and Physical Research  
Pavement Distress Manual

Low Severity Permanent Patch Deterioration

High Severity Permanent Patch Deterioration

Bureau of Materials and Physical Research  
Pavement Distress Manual

POTHOLES AND LOCALIZED DISTRESS

Description:

Potholes and localized distress are bowl-shaped holes of various sizes in the pavement surface. The bituminous material has broken into small pieces by fatigue cracking or by localized disintegration of the mixture and the material is removed by traffic.

Severity Levels:

Area (ft <sup>2</sup> )	Less than 1	1-3	Greater than 3
Depth (in)			
Less than 1	L	L	M
1-2	M	M	H
Greater than 2	M	H	H

Potholes that have been filled or partially filled by maintenance forces should be rated the same as an unfilled pothole, i.e., a filled pothole (2 ft<sup>2</sup>) with a remaining depth of 1.5" would be rated "M".

How to Record:

Potholes and areas of localized distress are recorded by the number of occurrences of each severity level within the sample units.

Note:

Potholes or localized failures associated with severe spalling of cracks are not recorded under this distress.

Bureau of Materials and Physical Research  
Pavement Distress Manual

Medium Severity Pothole

High Severity Pothole

Bureau of Materials and Physical Research  
Pavement Distress Manual

RAVELING / WEATHERING / SEGREGATION

Description:

Wearing away of the pavement surface caused by the dislodging of aggregate particles (raveling) and loss of asphalt binder (weathering). Segregation is the result of the coarse and fine components of the bituminous mix being separated in the pavement surface.

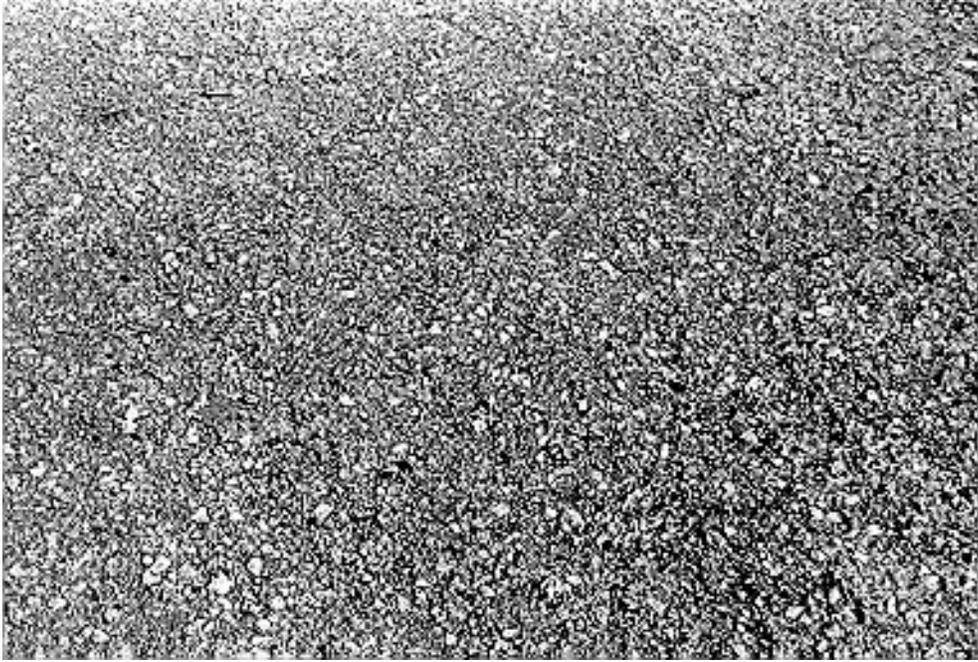

Severity Levels:

- L - Wearing away of the aggregate or binder has started but has not progressed significantly.
- M - Aggregate and/or binder has worn away and the surface texture is becoming rough and pitted; loose particles generally exist.
- H - Aggregate and/or binder has worn away and the surface texture is very rough and pitted.

How to Record:

Unit - Lane feet. Feet along the lane of the affected area at each severity level.

Bureau of Materials and Physical Research  
Pavement Distress Manual

Medium Severity Raveling and Weathering

High Severity Raveling and Weathering

# Bureau of Materials and Physical Research Pavement Distress Manual

## REFLECTED PATCH JOINT CRACKING

### Description:

Reflected patch joint cracks form along the edges of patches located in the underlying Portland cement concrete (PCC) pavement. In overlaid jointed concrete pavements these cracks usually appear as two parallel cracks less than ten feet apart and extending across the full lane width. For overlaid continuous reinforced concrete pavements and flexible pavements, the underlying patches may be of any size and shape.

### Severity Levels:

- L - Cracks are tight (mean width less than or equal to 1/4") with minor or no spalling present.
- M - Crack width is between 1/4" and 1/2". Cracks may be moderately spalled. Low severity random parallel cracking may exist near the crack or at the intersection of cracks.
- H - One or more of the following conditions exist: (1) crack width is greater than 1/2", (2) crack is severely spalled, (3) medium or severe random parallel cracking exists near the crack or at the intersection of cracks, (4) major sealing or other major maintenance activity has been performed.

### How to Record:

Reflected patch joint cracking is recorded as the number of occurrences at each severity level. A crack extending at least halfway across a lane constitutes one occurrence. A crack exhibiting various levels of severity is to be recorded as the highest level of severity present. If it is uncertain whether the crack is caused by an underlying patch, it should be treated as Transverse Cracking .

### Note:

Most sealed cracks are of high severity because of original crack width and/or severe spalling. In some cases, low and medium severity cracks have been sealed for preventive maintenance.

Bureau of Materials and Physical Research  
Pavement Distress Manual

Low Severity Reflected Patch Joint Cracking

# Bureau of Materials and Physical Research

## Pavement Distress Manual

### REFLECTION CRACKING OF TRANSVERSE JOINTS

#### Description:

This distress occurs only in bituminous surfaces over jointed Portland cement concrete (PCC) pavements. The distress occurs over the transverse joints in the underlying slab. This distress does not include reflection cracking away from a joint or from any other type of base material (i.e., cement, lime bituminous, or pozzolanic stabilized) as these cracks are identified as "Transverse Cracking". A knowledge of the slab dimensions beneath the bituminous overlay will help identify these cracks.

#### Severity Levels:

- L - Cracks are tight (mean width less than or equal to 1/4") with minor or no spalling present.
- M - Crack width is between 1/4" and 1/2". Cracks may be moderately spalled. Low severity random parallel cracking may exist near the crack or at the intersection of cracks.
- H - One or more of the following conditions exist: (1) crack width is greater than 1/2", (2) crack is severely spalled, (3) medium or severe random parallel cracking exists near the crack or at the intersection of cracks, (4) major sealing or other major maintenance activity has been performed.

#### How to Record:

Transverse joint reflection cracking is recorded as the number of occurrences at each severity level. A crack extending at least halfway across a lane constitutes one occurrence. A crack exhibiting various levels of severity is to be recorded as the highest level of severity present.

#### Note:

Most sealed cracks are of high severity because of original crack width and/or severe spalling. In some cases, low and medium severity cracks have been sealed for preventive maintenance.

Bureau of Materials and Physical Research  
Pavement Distress Manual

Medium Severity Reflection Cracking of Transverse Joints  
(sealed for preventive maintenance)

High Severity Reflection Cracking of Transverse Joints

Bureau of Materials and Physical Research  
Pavement Distress Manual

REFLECTIVE WIDENING CRACKING

Description:

Reflective widening cracking runs parallel to the pavement edge. This type of crack occurs two to four feet from the edge of both sides of the pavement and is very straight. In some cases, the crack may occur six to eight feet from one edge of the pavement, indicating all of the widening was placed on one side.

Severity Levels:

- L - Cracks are tight (mean width less than or equal to 1/4") with minor or no spalling-a present.
- M - Crack width is between 1/4" and 1/2". Cracks may be moderately spalled. Low severity random parallel cracking may exist near the crack or at the intersection of cracks.
- H - One or more of the following conditions exist: (1) crack width is greater than 1/2", (2) crack is severely spalled, (3) medium or severe random parallel cracking exists near the crack or at the intersection of cracks, (4) major sealing or other major maintenance activity has been performed.

How to Record:

Reflective widening cracking is measured in lineal feet. The length and severity level of each crack should be identified and recorded. If the crack does not have the same severity level along its entire length, each general portion should be recorded separately.

Note:

Most sealed cracks are of high severity because of original crack width and/or severe spalling. In some cases, low and medium severity cracks have been sealed for preventive maintenance.

Pavement Distress Manual

RUTTING

Description:

Rutting is longitudinal depressions in the wheelpaths. It may result from consolidation of the pavement materials and/or sideways movement of the bituminous mix.

Severity Levels:

No degrees of severity are defined.

How to Record:

Manual - A six foot beam is used to measure the rutting in both wheelpaths in the outer lane. Rutting is measured in 1/20" increments.

Automatic - The Video Inspection Vehicle (VIV) uses sensors to measure the distance between the bumper and the pavement. The rut depth is calculated automatically and stored in 1/10 mile increments.

Note:

The manual and automatic methods of measurement do not give the same rut depth. At this time, there is no correlation between the two methods. Caution should be used when comparing rut depths that were measured using different methods.

Bureau of Materials and Physical Research  
Pavement Distress Manual

SHOVING/CORRUGATION

Description:

Shoving/Corrugation is a form of plastic movement of bituminous material typified by ripples across the asphalt pavement surface. It occurs usually at locations where traffic starts and stops or where turning movements occur.

Severity Levels:

- L - The distress causes some vibration of the vehicle but creates no discomfort to passengers.
- M - The distress causes significant vibration of the vehicle, creating some passenger discomfort.
- H - The distress causes excessive vibration of the vehicle creating substantial discomfort, and/or a safety hazard, and/or vehicle damage, requiring a reduction in speed.

How to Record:

Shoving/Corrugation is measured as the length of pavement (lane feet) where the distress occurs anywhere within the lane. The highest severity level present within the width of the pavement should be recorded.

Bureau of Materials and Physical Research  
Pavement Distress Manual

TRANSVERSE CRACKING

Description:

Transverse cracks extend across the pavement perpendicular to the centerline. They are caused by cracks in the underlying pavement or stabilized base reflecting through the bituminous surface. The cracks may also be due to thermal cracking of the bituminous surface. Transverse cracking is usually not as straight as "Transverse Joint Reflection Cracking".

Severity Levels:

- L - Cracks are tight (mean width less than or equal to 1/4") with minor or no spalling present.
- M - Crack width is between 1/4" and 1/2". Cracks may be moderately spalled. Low severity random parallel cracking may exist near the crack or at the intersection of cracks.
- H - One or more of the following conditions exist: (1) crack width is greater than 1/2", (2) crack is severely spalled, (3) medium or severe random parallel cracking exists near the crack or at the intersection of cracks, (4) major sealing or other major maintenance activity has been performed.

How to Record:

Transverse cracking is recorded as the number of occurrences at each severity level. A crack extending at least halfway across a lane constitutes one occurrence. A crack exhibiting various levels of severity is to be recorded as the highest level present.

Note:

Most sealed cracks are of high severity because of original crack width and/or severe spalling. In some cases, low and medium severity cracks have been sealed for preventive maintenance.

## CONSTRUCTION JOINT DETERIORATION

### Description:

Construction joint distress is a breakdown of the concrete or steel at a CRCP construction joint. It often results in a series of closely spaced transverse cracks near the construction joint or a large number of interconnecting cracks. These cracks can, in time, lead to spalling and breakup of the concrete. If an inadequate steel lap or a steel rupture occurs at a construction joint, the result is often spalling and disintegration of the surrounding concrete, and a possible punchout. This can also lead to a readily accessible entrance for water. The primary causes of construction joint distress are poorly consolidated concrete and inadequate steel content or placement.

### Severity Levels:

- L - Only closely spaced tight cracks with no spalling or faulting occurring within 10 ft of each side of construction joint.
- M - Some low severity spalling of cracks, or a low severity punchout exists within 10 ft of either side of the construction joint. Temporary patching may have been placed.
- H - Significant deterioration and breakup exists within 10 ft of the construction joint that requires patching.

### How to Measure:

The number of construction joints at each severity level is noted and recorded.

Bureau of Materials and Physical Research  
Pavement Distress Manual

High Severity Construction Joint Deterioration

# Bureau of Materials and Physical Research

## Pavement Distress Manual

### D-CRACKING

#### Description:

D-cracking is a series of closely spaced hairline cracks that appear on the PCC pavement slab surface adjacent to transverse and longitudinal joints in jointed pavements and adjacent to the normal tight cracking pattern in CRC pavements. The surface cracks often appear as a darker stained area and may contain a white residue which leaches from the cracks.

#### Severity Levels:

- L - The characteristic crack pattern is evident along with staining and leaching. A fan shape spreading of the cracks is also evident. No spalling is present.
- M - The characteristic crack pattern is very evident and patterns at individual transverse cracks are beginning to joint together. Minor spalling is evident and the pavement produces a hollow sound when thumped.
- H - A high level of spalling is evident with maintenance patching required. Considerable loose material along the shoulders. Crack pattern formed between several adjacent transverse cracks.

#### Frequency Level:

- 1 - Less than 10 percent of the pavement surface shows the characteristic pattern for CRC pavements or pattern not evident along full length of transverse cracks or joints for jointed pavement.
- 2 - 10 to 50 percent of the pavement surface shows cracking pattern or full length of joints in jointed pavements show cracking with pattern extending an average of 12 to 24 inches from crack.
- 3 - More than 50 percent of the surface area of CRC pavements shows cracking or pattern extends more than 24 inches from joints on jointed pavements.

Bureau of Materials and Physical Research  
Pavement Distress Manual

## Pavement Distress Manual

### DEPRESSION

#### Description:

Depressions in concrete pavements are localized settled areas. There is generally significant slab Cracking in these areas due to uneven settlement. The depressions can be located by stains caused by oil drippings from vehicles and by riding over the pavement. Depressions can be caused by settlement or consolidation of the foundation soil or can be "built in" during construction. They are frequently found near culverts. This is usually caused by poor compaction of soil around the culvert during construction. Depressions cause slab cracking, roughness, and hydroplaning when filled with water of sufficient depth.

#### Severity Levels:

- L - Depression causes a distinct bounce of vehicle which creates no discomfort.
- M - Depression causes significant bounce of the vehicle which creates some discomfort.
- H - Depression causes excessive bounce of the vehicle which creates substantial discomfort, and/or a safety hazard, and/or vehicle damage, requiring a reduction in speed for safety.

#### How to Measure:

Depressions are measured by counting the number that exists in each uniform section. Each depression is rated according to its level of severity. Severity level is determined by riding in a mid- to full-sized sedan weighing approximately 3000-3800 lb. over the uniform section at the posted speed limit.

Bureau of Materials and Physical Research  
Pavement Distress Manual

FAULTING OF LONGITUDINAL JOINTS

Description:

Longitudinal joint faulting is a difference in elevation of two traffic lanes measured at the longitudinal joint. It is caused primarily by heavy truck traffic and settlement of the foundation.

Severity Levels:

Low - Average faulting less than 0.25 inches.

Medium - Average faulting between 0.25 and 0.75 inches.

High - Average faulting greater than 0.75 inches.

Frequency Levels-

1 - Less than 10% of the length affected.

2 - 10 to 50% of the length affected.

3 - More than 50% of the length affected.

Bureau of Materials and Physical Research  
Pavement Distress Manual

LONGITUDINAL CRACKING

Description:

Longitudinal cracks occur generally parallel to the centerline of the pavement. They are often caused by a combination of heavy load repetition, loss of foundation support and thermal and moisture gradient stresses.

Severity Levels:

L - Hairline (tight) crack with no spalling or faulting, or a well sealed crack with no visible faulting or spalling.

M - Working crack with a moderate or less severity spalling and/or faulting less than 1/2 inch.

H - A crack with width greater than 1 inch; a crack with a high severity level of spalling; or a crack faulted 1/2 inch or more.

How to Measure:

Cracks are measured in linear feet for each level of distress. The length and average severity of each crack should be identified and recorded.

Bureau of Materials and Physical Research  
Pavement Distress Manual

PATCH ADJACENT SLAB DETERIORATION

Description:

Deterioration of the original concrete slab adjacent to the permanent patch is given the above name. This may be in the form of spalling of the slab/patch joint, "D" cracking of the slab adjacent to the patch, or a corner break (or edge punchout) in the adjacent slab.

Severity Levels:

The severity is rated L, M, or H according to the severity level of the distress.

How to Measure:

The number of permanent patches with distress in the original slab adjacent to the patch at each distress level (i.e., corner break, "D" cracking, spalling) will be counted and recorded separately.

Bureau of Materials and Physical Research  
Pavement Distress Manual

PERMANENT PATCH DETERIORATION

Description:

A patch is an area where a portion or all of the original concrete slab has been removed and replaced with a permanent type of material (e.g., concrete, epoxy, hot mix asphalt/aggregate mixture). Only permanent patches should be considered.

Severity Levels:

- L - Patch has little or no deterioration. Cracks and edge joints are tight. Low severity spalling or raveling may exist. No faulting or settlement has occurred. Patch is rated low severity even if it is in excellent condition.
- M - Patch is somewhat deteriorated. Settlement less than 1/2 inch, cracking, rutting, or shoving- has occurred in an asphalt patch; concrete patch may exhibit spalling and/or faulting up to 1/2 inch around the edges and/or cracks.
- H - Patch is badly deteriorated either by cracking, faulting, spalling, rutting or shoving to a condition which requires replacement. Patch may present tire damage potential.

How to Measure:

The area of patches at each severity level within the sample unit are recorded. Patching is measured in square feet of area.

Bureau of Materials and Physical Research  
Pavement Distress Manual

Low Severity Permanent Patch Deterioration

# Bureau of Materials and Physical Research

## Pavement Distress Manual

### POPOUTS

#### Description:

A popout is a small piece of concrete that breaks loose from the pavement surface due to freeze-thaw action, expansive aggregate or non-durable aggregate.

#### Severity Levels:

No levels of severity are defined.

#### Frequency Levels:

- 1 - An average of less than 1 popout per square yard of affected pavement surface or less than 10% of the surface area affected.
- 2 - One to two popouts per square yard of affected surface area and 10 to 50% of the surface area affected.
- 3 - More than 2 popouts per square yard of affected surface area or more than 50% of the surface area affected.

Bureau of Materials and Physical Research  
Pavement Distress Manual

POTHOLES AND LOCALIZED DISTRESS

Description:

A localized distress is an area where the concrete has broken up into pieces, spalled or scaled. The localized distress takes many shapes and forms. Many times it occurs within an area between intersecting, Y-shaped or closely spaced cracks. A localized distress can occur anywhere on the slab surface, but is frequently located in the wheelpaths. Inadequate consolidation of concrete is often a primary cause of localized distress. This is primarily considered to be caused by a construction deficiency, whereas the Edge Punchout is primarily load associated.

Severity Levels:

Area (ft <sup>2</sup> )	Less than 1	1-3	Greater than 3
Depth (in)			
Less than 1	L	L	M
1-2	M	M	H
Greater than 2	M	H	H

Localized distresses that have been filled or partially filled by maintenance forces should be rated the same as an unfilled localized distress, i.e., a filled localized distress (2 ft<sup>2</sup>) with a remaining depth of 1.5" would be rated "M".

How to Measure:

The number of localized distress areas are counted and recorded at each severity level in the uniform section.

Bureau of Materials and Physical Research  
Pavement Distress Manual

Low Severity Localized Distress

# Bureau of Materials and Physical Research

## Pavement Distress Manual

### PUNCHOUTS

#### Description:

A punchout is first characterized by a loss of aggregate interlock at one or two closely spaced cracks (i.e., usually less than 48 inches apart) near the edge joint. The crack or cracks begin to fault and spall slightly which causes the portion of the slab between the closely spaced cracks to act essentially as a cantilever beam. As heavy truck load applications continue, a short longitudinal crack forms between the two transverse cracks about 24-60 inches from the pavement edge. Eventually the transverse cracks break down further, the steel ruptures and the pieces of concrete punch downward under load into the subbase and subgrade. There is generally evidence of pumping near edge punchouts, and sometimes extensive pumping. The distressed area will expand in size to adjoining cracks and develop into a very large area if not repaired. The edge punchout is the major structural distress of CRCP.

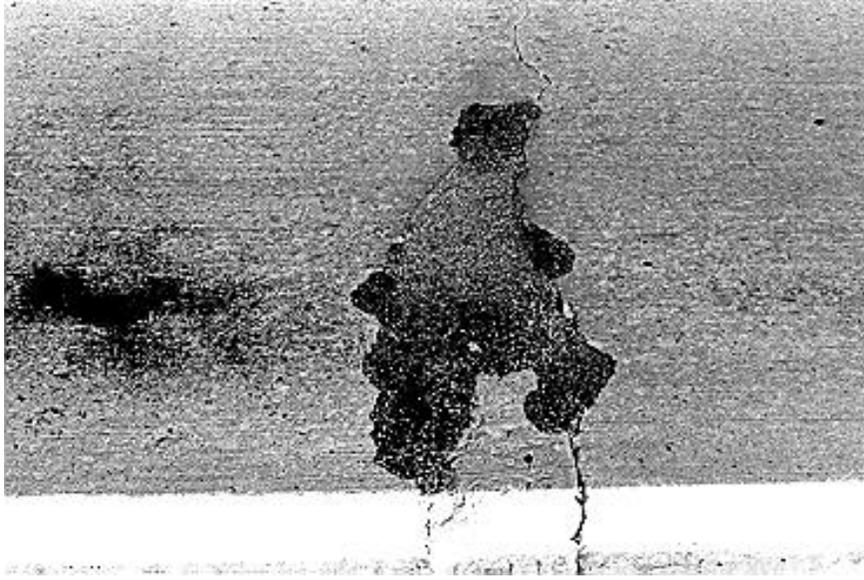

#### Severity Levels:

- L - A longitudinal crack develops between two closely spaced transverse cracks. The longitudinal and transverse cracks are fairly tight and only slight faulting or spalling is present.
- M - The transverse and/or longitudinal cracks have begun to widen and spall with faulting or punching down of the concrete less than 1/2 inch.
- H - The concrete within the boundary of the punchout is breaking up, has been punched down into the subbase more than 1/2 inch and/or has an asphalt patch on top. If the area has been patched with asphalt, it is still considered a punchout and not an asphalt patch since this is only a temporary patch.

#### How to Measure:

The number of punchouts and their level of severity are recorded for each sample unit.

Bureau of Materials and Physical Research  
Pavement Distress Manual

High Severity Punchout

Bureau of Materials and Physical Research  
Pavement Distress Manual

RANDOM LONGITUDINAL CRACKING

Description:

The lack of proper joint construction due to late sawing, inadequate depth of sawing, inadequate placement of inserts, etc., may result in random cracks developing in the slab. These cracks may occur very close to where the joint was supposed to be located, or they may meander a substantial distance from the intended joint. These cracks may lead to a major structural distress with heavy load repetitions.

Severity Levels:

L - Tight (hairline) crack with no spalling or faulting, or a well sealed crack with no visible faulting or spalling.

M- Working crack with moderate or less severity spalling and/or faulting less than 1/2".

H - A crack with width greater than 1 inch; a crack with a high severity level of spalling; or a crack faulted 1/2" or more.

How to Measure:

Random longitudinal cracking is measured in linear feet.

Bureau of Materials and Physical Research  
Pavement Distress Manual

Low Severity Random Longitudinal Cracking

Medium Severity Random Longitudinal Cracking

Bureau of Materials and Physical Research  
Pavement Distress Manual

SCALING AND MAP CRACKING OR CRAZING

Description:

Scaling is the deterioration of the upper 1/8-1/2 inch of the concrete slab surface. Map cracking or crazing is a series of fine cracks that extend only into the upper surface of the slab surface. Map cracking or crazing is usually caused by over-finishing of the slab and may lead to scaling of the surface. Scaling can also be caused by reinforcing steel being too close to the surface.

Severity Levels:

L - Crazing or map cracking exists over a majority of the slab area; the surface is in good condition with no scaling.

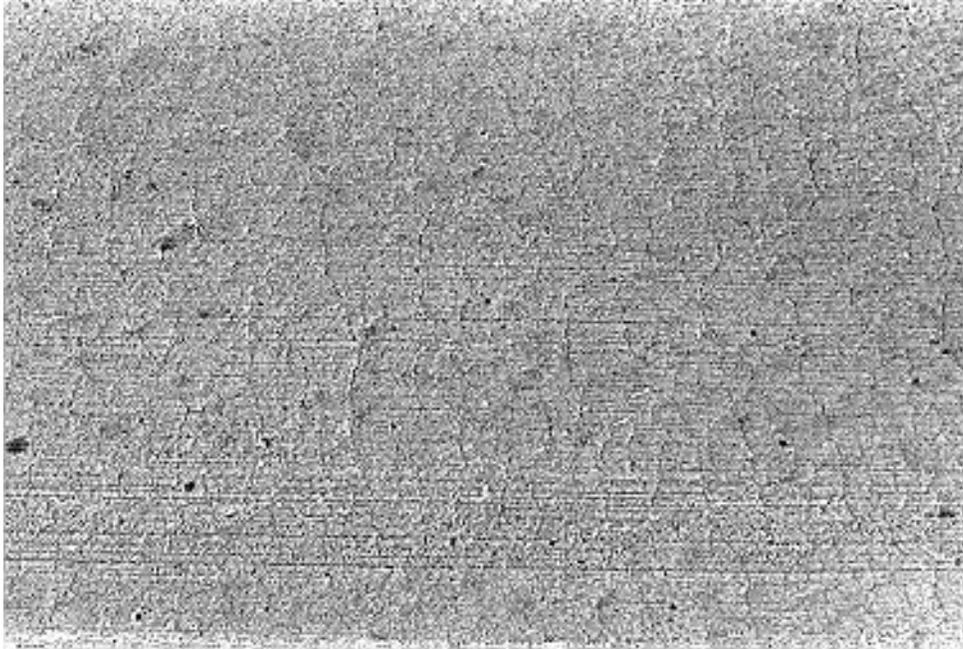

M - Less than 10% of any slab exhibits scaling.

H - More than 10% of any slab exhibits scaling.

How to Measure:

Scaling and map cracking or crazing are rated according to the highest severity level found in a sample unit.

Bureau of Materials and Physical Research  
Pavement Distress Manual

Low Severity Map Cracking

# Bureau of Materials and Physical Research

## Pavement Distress Manual

### SPALLING

#### Description:

Spalling of cracks and joints is the breakdown or fraying of the slab edges within 2 ft of the crack or joint. A spall usually does not extend vertically through the whole slab thickness, but extends to intersect the crack or joint at an angle. Spalling usually results from: (1) excessive stresses at the joint or crack caused by infiltration of incompressible materials and subsequent expansion, (2) disintegration of the concrete from durability problems, (3) weak concrete at the surface (caused by overworking or honeycombing), or (4) a keyed longitudinal joint failure.

#### Severity Levels:

- L - The spall or fray does not extend more than 3 inches on either side of the crack or joint. No temporary patching has been placed to repair the spall.
- M - The spall or fray extends more than 3 inches on either side of the joint or crack. Some pieces may be loose and/or missing but the spalled area does not present a tire damage or safety hazard. Temporary patching may have been placed because of spalling.
- H - The joint is severely spalled or frayed to the extent that a tire damage or safety hazard exists.

#### How to Measure:

Spalling of CRCP pavements is recorded under 5 distress types. Spalling of construction joints will be recorded under "Construction Joint Deterioration". Spalling of longitudinal joints and cracks and transverse cracks are recorded under "Spalling", "Transverse Cracks", and "Longitudinal Cracks". Spalling of the slab edge adjacent to a permanent patch will be recorded as "Patch Adjacent Slab Deterioration". Only the spalling of longitudinal and transverse joints is recorded under "spalling".

# Bureau of Materials and Physical Research

## Pavement Distress Manual

### SWELL

#### Description:

A swell is an upward movement or heave of the slab surface resulting in a sometimes sharp wave. The swell is usually accompanied by slab cracking. It is usually caused by frost heave in the subgrade or by an expansive soil. Swells can often be identified by oil drippings on the surface as well as riding over the pavement in a vehicle.

#### Severity Levels:

L - Swell causes a distinct bounce of the vehicle which creates no discomfort.

M - Swell causes significant bounce of the vehicle which creates some discomfort.

H - Swell causes excessive bounce of the vehicle which creates substantial discomfort, and/or a safety hazard, and/or vehicle damage, requiring a reduction in speed for safety.

#### How to Measure:

The number of swells within the uniform section are counted and recorded by severity level. Severity levels are determined by riding in a mid- to full-sized sedan weighing approximately 3000-3800 lb. over the uniform section at the posted speed limit.

# Bureau of Materials and Physical Research Pavement Distress Manual

## TRANSVERSE CRACKING

### Description:

Transverse cracking of continuously reinforced slabs is a normal occurrence and is not in itself considered to be a distress. As soon as the slab is placed and begins to harden, drying shrinkage of the concrete occurs. Reinforcement in the slab and subbase friction oppose the shrinkage and cracks soon form. After about 2-4 years, the crack spacing becomes constant. The purpose of the steel is to hold these random spaced transverse cracks tightly together so that load transfer across the crack will be obtained through aggregate interlock. If the steel ruptures or shears, load transfer across the crack is lost and the crack becomes a potential location for major distress. When deicing salts and water infiltrate through a wide crack, the reinforcing steel is subjected to corrosion and the effective diameter  $t$  of the steel begins to decrease. When the stresses due to temperature changes and loading are greater than the strength of the steel, the reinforcing bar ruptures. Indicators of sheared or decreased diameter reinforcing bars are faulted and/or widened spalled cracks. Some cracks may have widened substantially after steel rupture. (Note: Sometimes the transverse cracks run diagonally across the pavement and intersect. Hairline cracks that are less than 6 feet long are not rated.)

### Severity Levels:

Severity levels of transverse cracking are determined by crack spalling and faulting.

L - Tight (hairline) cracks with no faulting, steel rupture, or spalling.

M - A crack with no steel rupture, faulting less than or equal to 0.2 inch and/or low severity spalling.

H - Faulting greater than 0.2 inch, or steel rupture, or medium to high severity spalling.

### How to Measure:

Low severity cracks are counted for the first 100 feet and multiplied by 5 to approximate the number in the entire unit.

Medium and high severity cracks are counted individually for the entire unit.

Bureau of Materials and Physical Research  
Pavement Distress Manual

Low Severity Transverse Crack

# **Jointed Reinforced Concrete Pavement**

# Bureau of Materials and Physical Research

## Pavement Distress Manual

### CORNER BREAK

#### Description:

A corner break is a crack that intersects the joints at a distance less than 6 ft on each side measured from the corner of the slab. A corner break extends vertically through the entire slab thickness. It should not be confused with a corner spall which intersects the joint at an angle through the slab and is typically within 1 ft from the slab corner. Heavy repeated loads combined with pumping, poor load transfer across the joint, and thermal curling and moisture warping stresses result in corner breaks.

#### Severity Levels:

- L - Crack is tight (hairline). Well sealed cracks will be considered tight. No faulting or break-up at broken corner exists. Crack is not spalled.
- M - Crack is working and spalled at low or medium severity. Break-up of broken corner has not occurred. Faulting of crack or joint must be less than 1/2 inch. Temporary patching has been placed because of corner break.
- H - Crack is spalled at high severity or the corner piece has broken into two or more pieces. If faulting of crack or joint is more than 1/2 inch, it will be considered high severity.

#### How to Measure:

Corner breaks are measured by counting the number that exists in each inspection unit. Different levels of severity should be counted and recorded separately. Corner breaks adjacent to a patch will be counted "Patch Adjacent Slab Deterioration".

# Bureau of Materials and Physical Research

## Pavement Distress Manual

### D-CRACKING

#### Description:

"D" cracking is a series of closely spaced crescent-shaped hairline cracks that appear at a PCC pavement slab surface adjacent and roughly parallel to transverse and longitudinal joints, transverse and longitudinal cracks, and the free edges of pavement slab. The fine surface cracks often curve around the intersection of longitudinal joints/cracks and transverse joints/cracks. These surface cracks often contain calcium hydroxide residue which causes a dark coloring of the crack and immediate surrounding area. This may eventually lead to disintegration of the concrete within 1-2 ft or more of the joint or crack, particularly in the wheelpaths. "D" cracking is caused by freeze-thaw expansive pressures of certain types of coarse aggregates and typically begins at the bottom of the slab which disintegrates first. Concrete durability problems caused by reactive aggregates are rated under "Reactive Aggregate Distress".

#### Severity Levels:

- L - The characteristic pattern of closely spaced fine cracks has developed near joints, cracks, and/or free edges; however, the width of the affected area is generally less than 12 inches wide at the center of the lane in transverse cracks and joints. The crack pattern may fan out at the intersection of transverse cracks/joints with longitudinal cracks/joints. No joint/crack spalling has occurred, and no patches have been placed for "D" cracking.
- M - The characteristic pattern of closely spaced cracks has developed near the crack, joint or free edge and: (1) is generally wider than 12 inches at the center of the lane in transverse cracks and/or joints, or (2) low or medium severity joint/crack or corner spalling has developed in the affected area; or (3) temporary patches have been placed due to "D" cracking induced spalling.
- H - The pattern of fine cracks has developed near joints or cracks and (1) a high severity level of spalling at joints/cracks exists and considerable material is loose in the affected area, or (2) the crack pattern has developed generally over the entire slab area between cracks and/or joints.

#### How to Measure:

"D" cracking is measured and recorded in linear feet of free edges, cracks and joints affected. Different severity levels are counted and recorded separately. "D" cracking adjacent to a patch is rated as patch-adjacent slab deterioration. "D" cracking should not be counted if the fine crack pattern has not developed near cracks, joints and free edges. Popouts and discoloration of joints, cracks and free edges may occur without "D" cracking.

## Pavement Distress Manual

### DEPRESSION

#### Description:

Depressions in concrete pavements are localized settled areas. There is generally significant slab cracking in these areas due to uneven settlement. The depressions can be located by stains caused by oil drippings from vehicles, and by riding over the pavement. Depressions can be caused by settlement or consolidation of the foundation soil or can be "built in" during construction. They are frequently found near culverts. This is usually caused by poor compaction of soil around the culvert during construction. Depressions cause slab cracking, roughness, and hydroplaning when filled with water of sufficient depth.

#### Severity Levels:

- L - Depression causes a distinct bounce of the vehicle which creates no discomfort.
- M - Depression causes significant bounce of the vehicle which creates some discomfort.
- H - Depression causes excessive bounce of the vehicle which creates substantial discomfort, and/or a safety hazard, and/or vehicle damage, requiring a reduction in speed for safety.

#### How to Measure:

Depressions are measured by counting the number that exists in each uniform section. Each depression is rated according to its level of severity. Severity level is determined by riding in a mid- to full-sized sedan weighing approximately 3000-3800 lb. over the uniform section at the posted speed limit.

Bureau of Materials and Physical Research  
Pavement Distress Manual

FAULTING OF LONGITUDINAL JOINTS

Description:

Longitudinal joint faulting is a difference in elevation of two traffic lanes measured at the longitudinal joint. It is caused primarily by heavy truck traffic and settlement of the foundation.

Severity Levels:

Low - Average faulting less than 0.25 inches.  
Medium - Average faulting between 0.25 and 0.75 inches.  
High - Average faulting greater than 0.75 inches.

Frequency Levels:

- 1 - Less than 10% of the length affected.
- 2 - 10 to 50% of the length affected.
- 3 - More than 50% of the length affected.

Bureau of Materials and Physical Research  
Pavement Distress Manual

FAULTING OF TRANSVERSE JOINTS AND CRACKS

Description:

Faulting is the difference of elevation across a joint or crack. Faulting is caused in part by a buildup of loose materials under the approach slab near the joint or crack as well as depression of the leave slab. The buildup of eroded or infiltrated materials is caused by pumping from under the leave slab and shoulder (free moisture under pressure) due to heavy loading. The warp and/or curl upward of the slab near the joint or crack due to moisture and/or temperature gradient contributes to the pumping condition. Lack of load transfer contributes greatly to faulting.

Severity Levels:

No levels of severity are defined.

How to Measure:

Faulting is determined by measuring the difference in elevation of slabs at transverse joints and cracks for the slabs in the sample unit. Faulting is measured one foot in from the outside (right) slab edge of the outer lane. At 50 foot intervals, select a representative joint or crack and measure the fault depth. Ten readings should be taken per sample unit. These readings should be averaged and the result recorded. Sign convention: + when approach slab is higher than departure slab; - when the opposite occurs.

Bureau of Materials and Physical Research  
Pavement Distress Manual

LONGITUDINAL CRACKING

Description:

Longitudinal cracks occur generally parallel to the centerline of the pavement. They are often caused by a combination of heavy load repetition, loss of foundation support, and thermal and moisture gradient stresses.

Severity Levels:

L - Hairline (tight) crack with no spalling or faulting, or a well sealed crack with no visible faulting or spalling.

M - Working crack with a moderate or less severity spalling and/or faulting- less than 1/2 inch.

H - A crack with width greater than 1 inch; a crack with a high severity level of spalling; or, a crack faulted 1/2 inch or more.

How to Measure:

Cracks are measured in linear feet for each level of distress. The length and average severity of each crack should be identified and recorded.

Bureau of Materials and Physical Research  
Pavement Distress Manual

PATCH ADJACENT SLAB DETERIORATION

Description:

Deterioration of the original concrete slab adjacent to the permanent patch is given the above name. This may be in the form of spalling of the slab/patch joint, "D" cracking of the slab adjacent to the patch, or a corner break in the adjacent slab.

Severity Levels:

The severity level is rated L, M, or H according to the severity level of the distress.

How to Measure:

The number of patched joints with distress in the original slab adjacent to the patch(es) at each distress level (i.e., corner break, "D" cracking, spalling) will be counted and recorded separately.

## Bureau of Materials and Physical Research Pavement Distress Manual

### PERMANENT PATCH DETERIORATION (INCLUDING REPLACED SLABS)

#### Description:

A patch is an area where a portion or all of the original concrete slab has been removed and replaced with a permanent type of material (e.g., concrete, epoxy, hot mix asphalt/aggregate mixture). Only permanent patches should be considered.

#### Severity Levels:

- L - Patch has little or no deterioration. Some low severity spalling or raveling of the patch edges may exist. Faulting (concrete) patch or settlement (asphalt) patch across the slab-patch joint must be less than 1/4 inch. Patch is rated low severity even if it is in excellent condition.
- M - Patch has cracked (low severity level) and/or some spalling of medium severity level exists around the edges. Minor raveling, rutting, or shoving may be present. Faulting or settlement of 1/4 to 1/2 inch exists. Temporary patches may have been placed because of permanent patch deterioration.
- H - Patch is badly deteriorated either by cracking, faulting, spalling, rutting or shoving to a condition which requires replacement. Patch may present tire damage potential.

#### How to Measure:

The area and severity level of each patch are recorded.

Bureau of Materials and Physical Research  
Pavement Distress Manual

Medium Severity Permanent Patch Deterioration

# Bureau of Materials and Physical Research Pavement Distress Manual

## POPOUTS

### Description:

A popout is a small piece of concrete that breaks loose from the pavement surface due to freeze-thaw action, expansive aggregate or non-durable aggregate.

### Severity Levels:

No levels of severity are defined

### Frequency Levels:

- 1 - An average of less than 1 popout per square yard of affected pavement surface or less than 10% of the surface area affected.
- 2 - One to two popouts per square yard of affected surface area and 10 to 50% of the surface area affected.
- 3 - More than 2 popouts per square yard of affected surface area or more than 50% of the surface area affected.

Bureau of Materials and Physical Research  
Pavement Distress Manual

POTHOLES AND LOCALIZED DISTRESS

Description:

A localized distress is an area of slab where the concrete has broken up into pieces, spalled or scaled. The localized distress takes many shapes and forms. Many times it occurs within an area between intersecting, Y-shaped or closely spaced cracks. A localized distress can occur anywhere on the slab surface, but is frequently located in the wheelpaths. Inadequate consolidation of concrete is often a primary cause of localized distress. This is primarily considered to be caused by a construction deficiency.

Severity Levels:

Area (ft <sup>2</sup> ) Depth (in)	Less than 1	1-3	Greater than 3
Less than 1	L	L	M
1-2	M	M	H
Greater than 2	M	H	H

Localized distresses that have been filled or partially filled by maintenance forces should be rated the same as an unfilled localized distress, i.e., a filled localized distress (2 ft<sup>2</sup>) with a remaining depth of 1.5" would be rated "M".

How to Measure:

The number of localized distress areas are counted and recorded at each severity level in the uniform section.

# Bureau of Materials and Physical Research Pavement Distress Manual

## RANDOM LONGITUDINAL CRACKING

### Description:

The lack of proper joint construction due to late sawing, inadequate depth of sawing, inadequate placement of inserts, etc., may result in random cracks developing in the slab. These cracks may occur very close to where the joint was supposed to be located, or they may meander a substantial distance from the intended joint. These cracks may lead to a major structural distress with heavy load repetitions.

### Severity Levels:

L - Hairline (tight) crack with no spalling or faulting, or a well sealed crack with no visible faulting or spalling.

M - Working crack with a moderate or less severity spalling, and/or faulting less than 1/2 inch.

H - A crack with width greater than 1 inch: a crack with a high severity level of spalling; or a crack faulted 1/2 inch or more.

### How to Measure:

Random longitudinal cracking is measured in linear feet.

Medium Severity Random Longitudinal Cracking

Bureau of Materials and Physical Research  
Pavement Distress Manual

SCALING AND MAP CRACKING OR CRAZING

Description:

Scaling is the deterioration of the upper 1/8-1/2 inch of the concrete slab surface. Map cracking or crazing is a series of fine cracks that extend only into the upper surface of the slab surface. Map cracking or crazing is usually caused by over-finishing of the slab and may lead to scaling of the surface. Scaling can also be caused by reinforcing steel being too close to the surface.

Severity Levels:

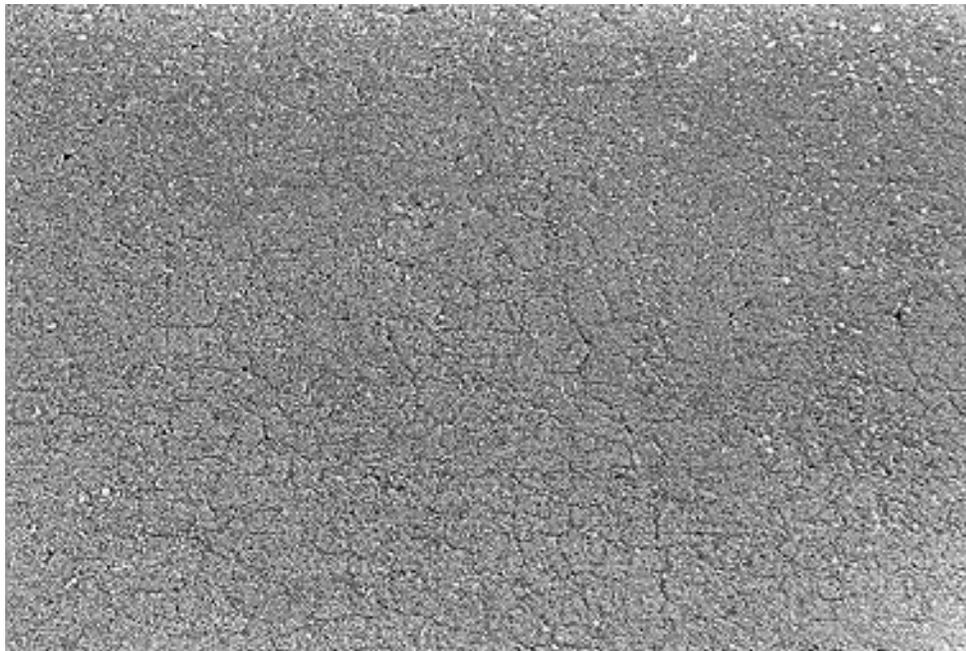

L - Crazing or map cracking exists over a majority of the slab area; the surface is in good condition with no scaling.

M - Less than 10% of any slab exhibits scaling.

H - More than 10% of any slab exhibits scaling.

How to Measure:

Scaling and map cracking or crazing are rated according to the highest severity level found in a sample unit.

Low Severity Map Cracking

# Bureau of Materials and Physical Research

## Pavement Distress Manual

### SPALLING

#### Description:

Spalling of cracks and joints is the cracking, breaking or chipping (or fraying) of the slab edges within 2 ft of the joint/crack. A spall usually does not extend vertically through the whole slab thickness, but extends to intersect the joint at an angle. Spalling usually results from: (1) excessive stresses at the joint or crack caused by infiltration of incompressible materials and subsequent expansion, (2) disintegration of the concrete from freeze-thaw action of "D" cracking, (3) weak concrete at the joint (caused by honeycombing), (4) poorly designed or constructed load transfer device (misalignment, corrosion), and/or (5) heavy repeated traffic loads.

#### Severity Levels:

- L - The spall or fray does not extend more than 3 inches on either side of the joint or crack. No temporary patching has been placed to repair the spall.
- M - The spall or fray extends more than 3 inches on either side of the joint or crack. Some pieces may be loose and/or missing, but the spalled area does not present a tire damage or safety hazard. Temporary patching may have been placed because of spalling.
- H - The joint is severely spalled or frayed to the extent that a tire damage or safety hazard exists.

#### How to Measure:

Spalling is measured by counting and recording separately, the number of occurrences at each severity level. Although the definition and severity levels are the same, spalling of cracks should not be recorded. The spalling of cracks is included in rating severity levels of cracks. Spall of the slab adjacent to a permanent patch will be recorded as patch adjacent slab deterioration. Only the spalling of longitudinal and transverse joints is recorded under "spalling."

# Bureau of Materials and Physical Research

## Pavement Distress Manual

### SWELL

#### Description:

A swell is an upward movement or heave of the slab surface resulting in a sometimes sharp wave. The swell is usually accompanied by slab cracking. It is usually caused by frost heave in the subgrade or by an expansive soil. Swells can often be identified by oil drippings on the surface as well as riding over the pavement in a vehicle.

#### Severity Levels:

L - Swell causes a distinct bounce of the vehicle which creates no discomfort.

M - Swell causes significant bounce of the vehicle which creates some discomfort.

H - Swell causes excessive bounce of the vehicle which creates substantial discomfort, and/or a safety hazard, and/or vehicle damage, requiring a reduction in speed for safety.

#### How to Measure:

The number of swells within the uniform section are counted and recorded by severity level. Severity levels are determined by riding in a mid- to full-sized sedan weighing approximately 3000-3800 lb. over the uniform section at the posted speed limit.

Bureau of Materials and Physical Research  
Pavement Distress Manual

TRANSVERSE CRACKING

Description:

Transverse cracks are caused by one or a combination of the following: heavy load repetition, thermal and moisture gradient stresses, and drying shrinkage stresses. Medium or high severity cracks are working cracks and are considered major structural distresses. (Note: Hairline cracks that are less than 6 feet long are not rated.)

Severity Levels:

- L - Hairline (tight) crack with no spalling or faulting, a well sealed crack with no visible faulting or spalling.
- M - Working crack with low to medium severity level of spalling and/or faulting less than 1/2 inch. Temporary patching may be present.
- H - A crack with width of greater than 1 inch; a crack with a high severity level of spalling; or, a crack faulted 1/2 inch or more.

How to Measure:

The number of cracks at each severity level are counted and recorded separately.

High Severity Transverse Crack (foreground) and  
Medium Severity Transverse Crack (background)

## Bureau of Materials and Physical Research Pavement Distress Manual

Name of Distress: Joint Seal Damage of Transverse Joints

Description: Joint seal damage is any condition which enables incompressible materials to infiltrate into the joints from the surface or allows significant infiltration of water. Accumulation of incompressible materials within the joints restricts in-slab expansion and may result in buckling, shattering, or spalling. A pliable joint filler bonded to the edges of the slabs protects the joints from accumulation of incompressible materials, and also reduces the amount of water seeping into the pavement structure. Typical types of joint seal damage are: (1) stripping of joint sealant, (2) extrusion of joint sealant, (3) weed growth, (4) hardening of the filler (oxidation), (5) loss of bond to the slab edges, and (6) lack or absence of sealant in the joint.

GOOD - Sealant is performing well with only a minor amount of any of the above types of damage present. Little water and no incompressibles can infiltrate through the joint.

FAIR - One or more of the above types of damage occurring to a moderate degree. Water can infiltrate the joint fairly easily; some incompressibles can infiltrate the joint. Sealant needs replacement within 3 years.

POOR - One or more of the above types of damage occurring to a severe degree. Water and incompressibles can freely infiltrate the joint. Sealant needs immediate replacement.

How to Measure: Joint seal damage of transverse joints is rated based on the overall condition of the sealant over the entire inspection unit.

## Bureau of Materials and Physical Research Pavement Distress Manual

Name of Distress:	Pumping and Water Bleeding
Description:	<p>Pumping is the ejection of material by water through joints or cracks, caused by deflection of the slab under moving loads. As the water is ejected, it carries particles of gravel, sand, clay, or silt, resulting in a progressive loss of pavement support. Surface staining or accumulation of base or subgrade material on the pavement surface close to joints or cracks is evidence of pumping. Pumping can occur without such evidence, particularly when stabilized bases are used. The observation of water being ejected by heavy traffic loads after a rain storm can also be used to identify pumping. Water bleeding occurs when water seeps out of joints or cracks.</p>
Severity Levels:	<p>LOW - Water is forced out of a joint or crack when trucks pass over the joints or cracks, water is forced out of the lane/shoulder joint when trucks pass along the joint, or water bleeding exists. No fines can be seen on the surface of the traffic lanes or shoulder.</p> <p>MODERATE - A small amount of pumped material can be observed near some of the joints or cracks on the surface of the traffic lane or shoulder.</p> <p>SEVERE - A significant amount of pumped materials exist on the pavement surface of the traffic lane or shoulder along the joints or cracks.</p>
How to Measure:	<p>If pumping or water bleeding exists anywhere in the sample unit it is counted as occurring at highest severity level noted.</p>

## Bureau of Materials and Physical Research Pavement Distress Manual

Name of Distress: Lane/Shoulder Joint Separation

Description: Lane/shoulder joint separation is the widening of the joint between the traffic lane and the shoulder generally due to movement in the shoulder. If the joint is tightly closed or well sealed so that water cannot easily infiltrate, then lane/shoulder joint separation is not considered a distress.

Severity Level: No severity level is counted if the joint is tightly sealed.

LOW - Some opening but less than or equal to 0.12 inch (3 mm).

MODERATE - More than 0.12 inch (3 mm) but equal to or less than 0.4 inch (10 mm) opening.

SEVERE - More than 0.4 inch (10 mm) opening.

How to Measure: Lane/shoulder joint separation is measured and recorded in inches (or mm) near transverse joints and at mid slab. The mean separation is used to determine the severity level.
